DISPLAY

1. INTRODUCTION

DISPLAY enables a data display facility for those routines which do not require complex display processing or cannot sacrifice the core for such a display. The routine displays any contiguous section of core via a moving window, with a cursor and octal read out of cursor positions to facilitate operator interaction.

2. ENVIRONMENT

2.1 Hardware

A PDP-12A computer.

2.2 Core Allocation

Any two PDP-8 pages in field Ø except page Ø that are segment contained, beta registers Ø, 1, and 2 of the segment, and any six page Ø locations are the core requirements. The actual binary output resides in one tape block.

3. CALLING PROCEDURE

There are two calls to DISPLAY: an initial call and a refresh call, both of which must be in the same PDP-8 field as DISPLAY (field \emptyset). The function of the initial call is to set up arguments for the refresh subroutines:

JMS I KIDORA

FIELD

CORE LOCATION

FIELD

CORE LOCATION

Y OFFSET

Y SCALE FACTOR

KIDORA, IDORA

The first four words are two 15-bit addresses that specify the beginning and end of the data buffer to be displayed, respectively. Any contiguous section of core is legal input to IDORA as long as the buffer is at least 1000_8 points long. The first address must be less than the second. DISPLAY treats the data buffer as a core ring so that the initial and terminal points are contiguously displayed.

The purpose of words 5 and 6 is to allow the calling programs flexibility in displaying data.¹ The fifth word is a Y off-set and specifies a 12 bit number to be added (2's compliment) to the data before it is displayed; the sixth word is a SCR K instruction and indicates the amount of scaling to be done prior to display. IDORA exits to the SCR K location in PDP-8 mode with the data field set to \emptyset and the AC = \emptyset .

The refresh call is simply

JMS I KRDORA

KRDORA, RDORA

The refresh call displays 1000_8 points, sets arguments for the next refresh and returns to the location following the call, in PDP-8 mode with the accumulator cleared and the data field DF and IF unchanged. Note that the initial call to DISPLAY must be to IDORA; RDORA always refreshes the buffer specified by the last call to IDORA

¹It should be noted that DISPLAY assumes the data to be in single word format.

4. FACTOR INTERACTION

The operator controls the position of the window with knob Ø: clockwise motion moves the window to the "right" or towards the end of the buffer; counter-clockwise, to the left. The midpoint reading on knob Ø causes the motion to stop.

Knobs 1 and 5 and Sense Switch (SSW) 5 control the cursor (an intensified dot). Depending on the setting of SSW 5, the cursor may either move along the curve or be displayed independently. When SSW 5 = Ø, the cursor moves along the curve and its position is controlled with Knob 1:

When Knob 1 is turned to its furthermost clockwise position, the cursor sits upon the rightmost scope point; when Knob 1 is positioned to its furthermost counter-clockwise position, the cursor sits on the leftmost scope point; intervening knob positions yield intervening cursor positions.

When SSW5 = 1, the cursor is displayed independently of the curve. For this case, Knob 1 controls the horizontal coordinate and Knob 5 the vertical coordinate. Horizontal displacement of the cursor via Knob 1 is identical to that described above. When Knob 5 is at its furthermost clockwise position, the cursor is displayed at the top of the scope. When Knob 5 is at its furthermost counter-clockwise position, the cursor is displayed at the bottom of the scope.

Associated with the cursor are four octal words displayed in the top left corner of the scope, one beneath the other¹. The first two words are the absolute 15-bit core address of the cursor point. The third word is the contents of the displayed core address, i.e., the actual 12-bit value in the data buffer of the data word that corresponds to the cursor point. The fourth word is the scope Y coordinate of the cursor point. The fourth word is a relative value and depends upon the Y scale factor and Y offset. If the data had been scaled to nine bits prior to display, the fourth word or Y coordinate would range from 0001 to 1000_8 , where 0001 corresponds to the bottom of the scope and 1000 corresponds to the top.

To facilitate interaction with the calling program the four displayed words described above are maintained in page \emptyset and may be accessed after the refresh return.

<u>TAG</u>	<u>CONTENTS</u>
XCURHI	Fifteen bit address of the point
XCURLO	in memory reference by the cursor
CORVAL	Contents of memory
YCUR	Relative Y display coordinate

¹The character size of the display depends upon the setting of the special functions register at the time the display is refreshed.

Standard Parameters

The six locations on page \emptyset can be anywhere and they do not have to be contiguous. The standard version of DISPLAY assumes locations 2 \emptyset - 25; the locations are defined via direct assignment statements at the end of the DISPLAY source.

YSHFT = 2 \emptyset	CONTAINS Y OFFSET
XCURHI = YSHFT + 1	}
XCURLO = XCURHI + 1	
CORVAL = XCURLO + 1	
YCUR = CORVAL + 1	
COUNT = YCUR + 1	

SEE ABOVE

The following symbols (also defined at the end of the DISPLAY source) may be redefined if the user wishes to use Knobs other than \emptyset , 1, and 5:

WINSAM = SAM \emptyset
CURSAM = SAM 1
FRESAM = SAM 5

As coded, DISPLAY occupies locations 54 $\emptyset\emptyset$ through 5777, with IDORA = 54 $\emptyset\emptyset$ and RDORA = 5544. The origin statement at line 1 \emptyset and/or the PAGE pseudo-op at line 223 may be altered to relocate part or all of DISPLAY. (N.B. if using the page of the segment containing the beta registers, place the origin at the fourth location of the page since DISPLAY uses beta registers \emptyset , 1, and 2; i.e. * 2 $\emptyset\emptyset$ 3; or * 4 $\emptyset\emptyset$ 3; or * 6 $\emptyset\emptyset$ 3).

Example

If Segments 4 and 5 contain 12 bit, unsigned data, the following would display 512 points (as controlled by knob Ø) until a keyboard input is detected:

JMS I KIDORA	/N.B. PDP-8 MODE
1	/LOCATION 1Ø,ØØØ.
Ø	/START OF BUFFER
1	/LOCATION 13,777 IS
3777	/END OF BUFFER
4ØØØ	/VERTICAL COORDINATOR
	/377 1ØØØ
SCALE 3	/ Ø TO 4ØØ
JMS I KRDORA	/4ØØ 1
KSF	/FROM 12 BITS TO 9
JMP LOOP	/REFRESH SCOPE
.	/KEY STRUCK ?
.	/NO, CONTINUE DISPLAY
.	The program might now do something with the datum indicated by the cursor exit, or
KIDORA, IDORA	/INITIALIZE POINTER
KRDORA, RDORA	/REFRESH POINTER

5. INTERNAL DESCRIPTION

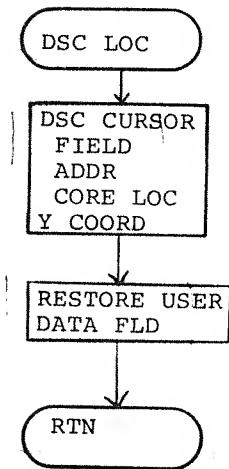

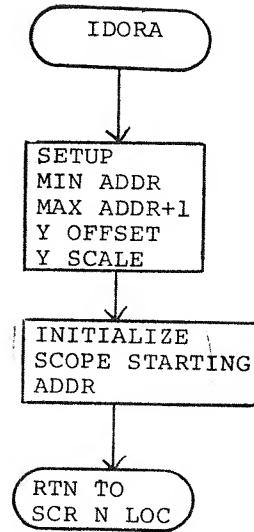

5.1 IDORA

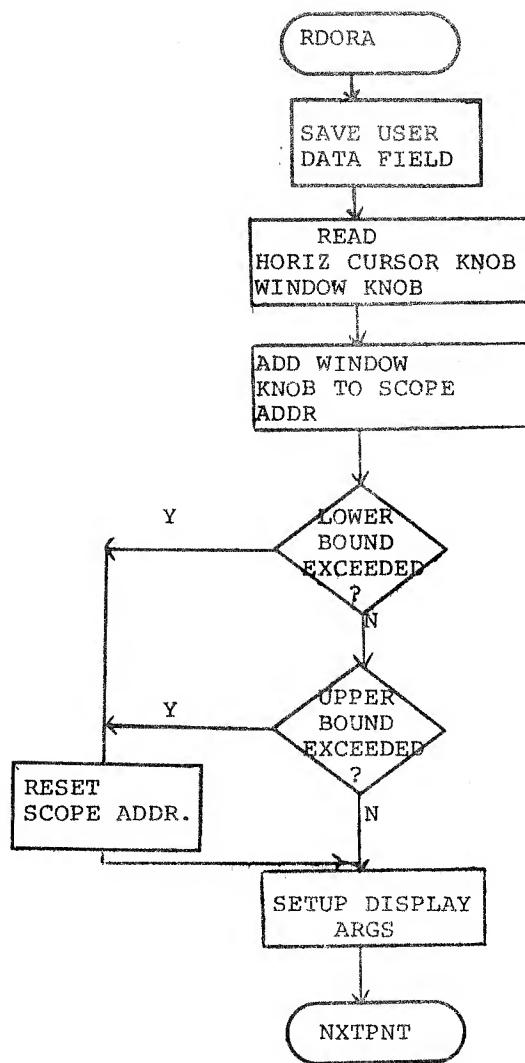

The function of IDORA is to retrieve the arguments from the initial call and set them up for RDORA. The lower bound is stored at MINFLD. MINADR, the upper bound + 1, is stored at MAXFLD, MAXADR. The Y offset is stored at YSHFT (page \emptyset) and the scale factor is stored at YSCAL.

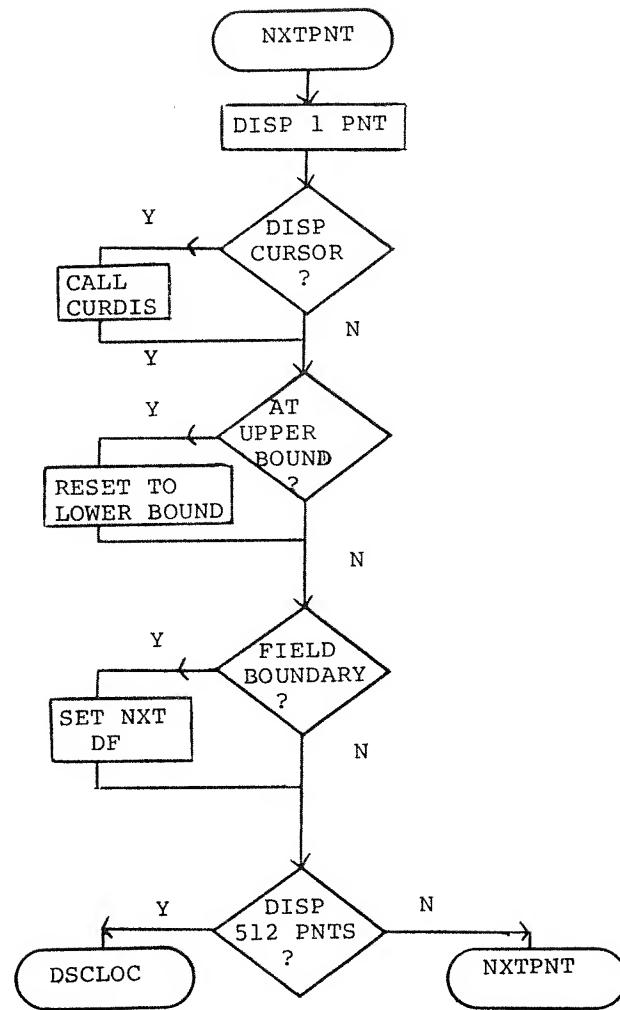

5.2 RDORA

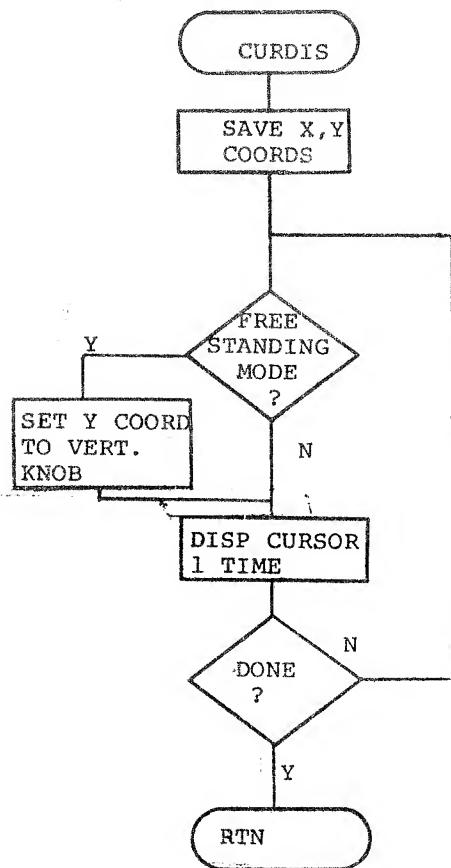

The function of RDORA is to display 1000_8 points relative to the window knob and a scope starting address and return. RDORA first reads the horizontal cursor knob and sets it to a value between -1 and -1000_8 ; this is the cursor count. RDORA then reads the window knob and updates the initial scope address (BUFHI, BUFLO) maintaining that address modulo the upper and lower bounds. RDORA then displays the buffer one point at a time. After each point is displayed, RDORA checks (IS#) the cursor count; when it goes to \emptyset , the cursor is displayed. RDORA also checks for the end of the display buffer and the end of a field, resetting to the start of the display buffer or to the next field respectively, as the case may be. After all points have been displayed, the routine DSCLOC is called to display the four words in the upper left corner of the scope. RDORA then restores the user's data field and returns.
