## CHAPTER 12

## VT8-E HIGH SPEED VIDEO DISPLAY TERMINAL AND CONTROL

## SECTION I INTRODUCTION

The VT8-E, a video display option for the PDP-8/E, PDP-8/F, and PDP-8/M, consists of a display monitor and three quad modules that plug into the OMNIBUS. The quad modules control the display monitor operation and can interface the VT8-E to either an LA30A-P DECwriter or an LS01-E Centronics Line Printer. Up to four VT8-E display options can be used simultaneously with the same computer.

The display monitor comprises a CRT with its associated power supply, deflection circuits and video circuits, and a Teletype ${ }^{\circledR}$ keyboard with its control logic. The monitor is contained in a desk-top enclosure (Figure 12-1).

Data is transferred from the monitor keyboard to the computer AC Register by program interrupts. Data to be displayed by the monitor is transferred from memory by Single Cycle Data Breaks to the VT8-E OMNIBUS control modules. The control modules convert the parallel data to serial video information that is displayed on the viewing screen. The monitor can display both alphanumeric characters and graphic symbols, either alone or in combination.

Figure 12-1 VT8-E Display Monitor

[^1]Neither the LA30A.P nor the LS01-E line printers is discussed here. Details concerning these two printers should be obtained from the respective maintenance manuals. Publications and documents relevant to the VT8-E are:
a. PDP-8/E and PDP-8/M Small Computer Handbook - DEC, 1972
b. PDP-8/E, PDP-8/F, and PDP-8/M Maintenance Manual, Volume 1
c. VT8-E Diagnostic; MAINDEC-08-DHVTB-A (Graphic), MAINDEC-08-DHVTA-A (Alphanumeric)
d. DEC Engineering Drawings, E-CS-M8335-0-1, E-CS-M8336-0-1, and E-CS-M8337-0-1 (interface modules)
e. DEC Engineering Drawing, D-CS-5409917-0-1 (DEC Keyboard \#2)
f. DEC Engineering Drawings, D-CS-3010326-1-0 (Motorola Raster Display)

### 12.1 SYSTEM OPERATING SPECIFICATIONS

| Operating Temperature Range | $5^{\circ}$ to $43^{\circ} \mathrm{C}$ |
| :---: | :---: |
| Operating Humidity Range (without condensation) | 10\% to 90\% (Relative) |
| Power Requirements (display monitor) | $100-130 \mathrm{Vac}, 50$ or 60 Hz <br> $\pm 5 \%$ single phase at 2 A <br> $200-260 \mathrm{Vac}, 50$ or 60 Hz <br> $\pm 5 \%$ single phase at 1 A |
| Power Consumption (display monitor) | 55 W at 115 V <br> 65 W at 230 V |

### 12.1.1 CRT Operating Specifications (Motorola Raster Display)

| Screen Size | $10-1 / 8 \mathrm{in} . \times 7-5 / 8 \mathrm{in}$. |
| :--- | :--- |
| Phosphor | P 4 (white) |
| Deflection Type | Magnetic |
| Deflection Method | Raster Scan |
| Input Impedance <br> (at VIDEO IN input) | $75 \Omega \pm 5 \%$ |
| Video Input Signal | 0.9 to 2.2 V with separate horizontal and vertical SYNC. |
| Video Pulse Rise and Fall Time | 40 ns $\langle 10 \%$ to $90 \%$ point), measured at cathode with 1.0 V <br> p-p input and 30 V p-p output. |
| Video Output Amplitude | 30 V p-p (minimum), measured at cathode with 1.0 V p-p input. |
| Resolution | Screen Center -600 lines (minimum) <br> Screen Corners -400 lines (minimum) (using shrinking raster <br> method) |

\(\left.\begin{array}{ll}Horizontal Sweep Frequency \& 15.6 \mathrm{kHz} <br>
Vertical Sweep Frequency \& 50 or 60 \mathrm{~Hz} (selectable) <br>
Horizontal Retrace \& 11 \mu \mathrm{~s} (maximum) <br>
Vertical Retrace \& 21 horizontal lines @ 15.6 \mathrm{kHz} <br>
High Voltage \& 11 \mathrm{kV} (minimum) @ 50 \mu \mathrm{~A} beam current @ 24 \mathrm{Vdc} power <br>

supply adjustment\end{array}\right\}\)| $12 \mathrm{M} \Omega$ (maximum), for a beam current change from 50 to |
| :--- |
| High Voltage Regulation |
| CRT Refresh Rate |

### 12.1.2 Visible Display Specifications

| Screen Refresh Rate | 60 or 50 frames $/ \mathrm{sec}$ (determined <br> by local line frequency) |
| :--- | :--- |
| Refresh Method | Raster Scan |

12.1.2.1 Alphanumeric Mode

| Viewing Area | 8-1/4 in. (horiz) $\times 6-1 / 4$ in. (vert <br> (32 characters/line) <br> $8-1 / 4 \mathrm{in}$. $\times 4-1 / 4 \mathrm{in}$. ( 64 charact |
| :---: | :---: |
| Character Lines | 20 |
| Character Size | 0.185 in. width <br> 0.220 in. height <br> (32 characters/l |
|  | $\begin{aligned} & 0.090 \text { in. width }(64 \text { characters/l } \\ & 0.150 \text { in. height } \end{aligned}$ |
| Character Spacing |  |
| Horizontal | 0.0740 in. ( 32 characters/line) <br> 0.0370 in. ( 64 characters/line) |
| Vertical | 0.0946 in. ( 32 characters/line) <br> 0.0645 in. ( 64 characters/line) |
| Character Set | 64-character ASCII set (upper case) |
| Character Generation Method | $5 \times 7$ dot matrix |

### 12.1.2.2 Graphic Mode

## Viewing Area

7 in. $\times$ 6-1/4 in. (if wired for 32 alphanumeric characters per line)

Display Lines

Flicker-Free Points per Line

200

189

## SECTION 2 INSTALLATION AND ACCEPTANCE TEST

The VT8-E Video Display and Control are installed on site by DEC Field Service personnel. The customer should not attempt to unpack, inspect, install, checkout, or service the equipment.

### 12.2 UNPACKING

The VT8-E Display Monitor is packed in a specially designed carton to avoid damage during shipment.
NOTE
Carefully examine the VT8-E for damage as it is unpacked. Any damage should be reported immediately.

Unpack the VT8-E Display Monitor as follows:
Step
Procedure

1 Remove the Display Monitor from the shipping container.
2 Remove the polyethylene cover.
3 Remove any tape, etc., from the display monitor cabinet.
4 Remove the display monitor from the shipping skid.
5 Place the display monitor in the desired location.
6 Verify all items listed on the Inventory List shipped with the VT8-E have been received.

### 12.2.1 Primary Power

The Display Monitor uses a single ac power cable (permanently connected) to connect the site power source to the display monitor. The monitor operates at $110-130 \mathrm{Vac}, 50-60 \mathrm{~Hz}$, single phase, or $200-260 \mathrm{Vac}, 50-60 \mathrm{~Hz}$, single phase.

Each wire in the ac power cable is color-coded as shown in Table 12-1. The display monitor is normally supplied with a 15 A connector. The selected ac service outlet must be capable of at least $2 \mathrm{~A}, 110 \mathrm{Vac}, 50$ or 60 Hz , or 1A, $200 \mathrm{Vac}, 50$ or 60 Hz .

Table 12-1
AC Power Cable

| Line | Wire Color | Terminal Strip <br> Nomenclature |
| :--- | :--- | :--- |
| Frame Ground <br> Neutral/Line 2 <br> Line 1 | Green <br> White <br> Black | Frame Ground |

### 12.2.2 VT8-E Installation

Install the VT8-E as follows:

Ensure PDP-8/E power is off.

Ensure the Display Monitor Power Select switch, located on the side of the Display Monitor, is set correctly for the power source (115 Vac or 230 Vac ).

Use a meter to measure the voltages on the wall receptacle and ensure that the hot, neutral, and ground connections are the same as those on the Display Monitor power connector (Table 12-1).

On the M8336 and M8337, ensure the 5 jumpers are installed to select only 64 or 32 characters per line. All jumpers must be installed for the same mode.

On the M8335 module ensure the correct device code jumpers are installed. Table 12-2 contains a list of the split lugs which should be connected in each of the 6 groups ( $A-F$ ) to select one of the 64 possible device codes. Split lug locations (by groups) are shown on D-CS-M8335-0-1-Engineering Drawing cover sheet.

On the M8337 and M8335 modules, ensure the jumpers are installed correctly to select the priority assigned to this VT8-E (Table 12-3). Only priorities 9 (highest), 10, and 11 (lowest) may be assigned to the VT8-E. Refer to M8337-0-1 and M8335-0-1 cover sheet for jumper locations.

Connect J1 of the 7009042 Cable Assembly to J1 on the M8336 module.
Connect J2 of the 7009042 Cable Assembly to J1 on the M8335 module.
If a line printer is used, connect the printer cable assembly to J 2 on the M8335 module.
Install the VT8-E modules on the OMNIBUS as shown in Figure 12-2. Refer to Figure 2-3 in Volume 1 for recommended module installation priorities. The VT8-E is not a memory option. The VT8-E modules must be installed in this order;

| M8336 | Front |
| :--- | :--- |
| M8337 | Middle |
| M8335 | Rear |

Install H851 Top Connectors as follows (Figure 12-2):
a. Between M8336H and M8337H
b. Between M8337E and M8335E
c. Between M8337F and M8335F

Route the 7009042 Cable Assembly to the Display Monitor and connect J3 Winchester Connector to the mating connector on the rear of the console.

NOTE
If more than one VT8-E is installed in one system (up to four may be installed in one system), the second control goes on the OMNIBUS directly behind the first, and the third behind the second, etc. The two controls are interconnected by installing an H851 Top Connector between M8335J of the first control and M8336J of the second control. The controls must be assigned different device codes (Tables 12-2 and 12-3).

Turn on PDP-8/E power and run the acceptance test in Paragraph 12.2.4.

Table 12-3
Priority Jumper Installation

| Priority | M8337 Install <br> Jumper | M8335 Install <br> Jumpers |
| :--- | :---: | :--- |
| 9 (highest) | W 1 | $\mathrm{P9}$ and P10 |
| 10 | W 2 | $\mathrm{P}^{\prime}$ and P 10 |
| 11 (lowest) | W 3 | $\mathrm{P}^{\prime}$ and $\mathrm{P10}$ |

Figure 12-2 VT8-E Module Installation

### 12.2.3 Acceptance Test

The VT8-E is checked for proper operation by running the two diagnostic programs. Both MAINDECs referenced in the introductory remarks and the A-SP-VT8-E engineering specification give detailed instructions for their performance in the instructions shipped with the paper tapes. If problems arise, refer to the maintenance instructions, both in this manual and in Volume 1.

## SECTION 3 OPERATION AND PROGRAMMING

This section provides a functional description of the VT8-E logic, operation and programming information, a list of IOT instructions, and some VT8-E programming examples.

### 12.3 FUNCTIONAL DESCRIPTION

Each of the functional groups of logic in the VT8-E are described in the following paragraphs (Figure 12-3). Their purpose, location (on what module), and function are provided to familiarize the reader with VT8-E operation. A detailed description of VT8-E logic and timing is given in Chapter 4. Refer to Chapter 9 of the Small Computer Handbook - DEC, 1972 for information about data transfers via IOT instructions and data breaks. A detailed block diagram of the VT8-E which shows data flow and the interrelationship of the functional groups is in the VT8-E Video Display Control Engineering Drawings.

### 12.3.1 VT8-E Printer/Keyboard Control Module (M8335)

The functional groups of logic on the M8335 module are discussed in the following paragraphs.
12.3.1.1 MD Bus Gating - Data from the MD lines is applied to the M8337 module by I/O PAUSE if IOT instructions are executed by the program or by MD EN during Single Cycle Data Breaks. Single Cycle Data Break is the method used to transfer data between memory and the display control (Paragraph 12.3.4.1).

Figure 12-3 VT8-E Block Diagram
12.3.1.2 IOT Decoders - The M8335 module contains two IOT decoders, one for the printer and one for the keyboard. The decoders are assigned different device codes so that the printer IOT decoder is selected when printer IOTs are programmed, and the keyboard IOT decoder is selected when keyboard IOTs are programmed. The keyboard and printer may be assigned any two of the device codes listed in Table 12-2. The device codes assigned to the keyboard and printer must be different from each other and different from the display device code. The IOT decoders decode MD9-MD11 from the MD lines and generate control signals to control keyboard and printer operations; i.e., data transfers. The keyboard and printer instructions are listed in Paragraph 12.3.4.
12.3.1.3 Data Bus Gating - The Data Bus gates are enabled and DATA0-DATA11 are applied to the M8337 logic when the following occur:
a. If the program executes the PNPC or PNLP instructions to load the Printer Buffer.
b. If the program executes a DPLA instruction to load the Starting Address Register or a DPG0 instruction to load the Extended Starting Address Register.
c. During a Single Cycle Data Break. DATO-DATA8, 9, or 10 monitored by the VT8-E during data breaks to determine if the VT8-E has the highest priority for a data break.
12.3.1.4 Keyboard Buffer - The Keyboard Buffer receives a 7-bit ASCII code from the keyboard when one of the keys on the keyboard is pressed. The keyboard also generates a KEYBOARD STROBE which enables the 7-bit ASCII code to be transferred to the buffer and sets the KYBD flag. When the KYBD flag is set, an INT ROST is made if interrupts are enabled, or a SKIP if the DKSF instruction is executed by the program. An INT ROST or SKIP notifies the program that data in the Keyboard Buffer is available to be read into the AC. The program must transfer the data in the buffer to the AC and clear the KYBD flag so that a new 7-bit ASCII character can be transferred from the keyboard to the buffer.
12.3.1.5 I/O Transfer Control - The I/O Transfer Control logic determines the direction of data flow on the Data Bus and whether the AC is cleared or not. C0 and C1 (the C lines) are asserted by IOT instructions which transfer data to or from the $A C$.
12.3.1.6 Interrupt and Skip Logic - The Interrupt and Skip logic allows the program to enable the interrupts and generate an INT ROST when the KYBD and PRINT DONE flags are set or to check the flags using a SKIP instruction; i.e., the DKSF instruction.
12.3.1.7 Interrupt Logic - The Keyboard and Printer Interrupt logic is enabled if bit 11 in the $A C$ is set (1) when the DKIN instruction is executed by the program. If the interrupts are enabled, an INT ROST is made when the KYBD flag is set or the PRINT DONE flag is set. The KYBD flag is set when a keyboard key is pressed, and the PRINT DONE is set when the printer has finished printing a character.
12.3.1.8 Starting Address Register and Counter (SAR) - The Starting Address Register (SAR) is a 12-bit register that is loaded from the AC with the memory address of the first word to be transferred by the Single Cycle Data Break facility. The contents of SAR are transferred to the Starting Address Counter after the DPGO instruction is executed by the program and the counter is incremented at the end of each data break to select the next sequential memory address. The contents of the counter are applied to the Memory Address lines (MA0-MA11) to address a location in memory.
12.3.1.9 Extended Starting Address Register - The Extended Starting Address Register (XSAR) is loaded from bits 6,7 , and 8 of the AC by the DPGO instruction. The contents of XSAR are transferred to the XSAR Counter and used to select a field in memory for data transfers. The XSAR is incremented when the SAR overflows to select the next memory field. At this time the SAR starts reading memory locations in the newly selected memory field.
12.3.1.10 Printer Buffer - The Printer Buffer is a 7 -bit register that is loaded from the AC by the PNLP instruction. The data from the AC contains a 7-bit ASCII code for a character to be printed. The seven data bits are transferred along with a PRINT STROBE pulse, and when the Print operation is completed, the PRINT DONE flag is set. If interrupts are enabled, an INT ROST is made at this time, or if the flag is checked by the PNSK instruction, the SKIP line is grounded. The program may perform a routine to transfer another character to the printer at this time.
12.3.1.11 PRINT DONE Flag - The PRINT DONE flag is set each time the printer completes a print operation to inform the program that the printer is ready to accept a new character.
12.3.1.12 Higher Priority Detection - The Higher Priority Detection logic monitors the Data Bus to determine if the VT8-E has the highest priority for a data break. If there are any peripherals connected to the OMNIBUS that have a higher priority than the VT8-E, one of the lines on the Data Bus will be low to prevent the VT8-E from doing a data break. As an example, if the peripheral assigned the highest priority wants to do a data break, DATAO is asserted (low) and the VT8-E cannot do a data break until DATAO goes high at the completion of the other peripheral's data break. When the VT8-E is ready to do a data break, DATA9, DATA10, or DATA11 will be asserted low to prevent peripherals with a lower priority from doing a data break before the VT8-E. As can be seen from the previous discussion, the VT8-E may be assigned one of the three lowest priorities.

### 12.3.2 VT8-E Line Buffer Module (M8337)

The functional groups of logic located on the VT8-E Line Buffer Module are discussed in the following paragraphs.
12.3.2.1 Line Buffers A and B - Line Buffers A and B provide temporary storage of 32 or 64 words from memory in the Alphanumeric mode or 32 words from memory in the Graphic mode. In the Alphanumeric mode the word from memory (Figure 12-7) selects the visible field, display mode, and character to be displayed. In the Graphic mode, the word from memory ( 16 words per line) consists of 1 s (display a dot) and 0 s (do not display a dot) to produce a line on the face of the CRT. The display mode (Alphanumeric or Graphic) is selected by bit $10(0 \rightarrow$ ALPHA and $1 \rightarrow$ GRAPHIC) from the AC when the DPGO instruction is executed by the program.

Each alphanumeric character is displayed on the face of the CRT in a 5 (width) $\times 7$ (height) dot matrix. To display one row of characters ( 32 or 64 characters), the Display Monitor makes 10 horizontal sweeps across the face of the CRT. The first two scans are used to load the Line Buffers from memory via the Single Cycle Data Break. The third scan addresses a blank ROM location and the remaining seven scans display the alphanumeric data. The first of the seven scans displays the first line of each character in the row of characters to be displayed, the second scan the second line, etc., until seven scans are completed to display a row of characters ( 32 or 64 ). When the tenth scan is completed, the program must set up for a new break and initiate a new break cycle to reload the Line Buffers if additional rows of characters ( 20 maximum) are to be displayed. During the display operation the 7 -bit ASCII code (Figure 12-7) is decoded by the ASCII decoding ROMS to generate the video signals to be displayed and the four control bits are decoded to determine the display mode and visible field. A display may be stopped after any number of characters have been displayed, if the display is less than 20 rows, to save computer time. This is done by setting CB1 and CB2 to 1 s when the last character is displayed.

In the Graphic mode, data is displayed on the face of the CRT in a 189 (width) $\times 200$ (height) dot matrix. Each line ( 189 dots) requires 1612 -bit words. The last three bits of the sixteenth word are not used. Each bit of the data word represents a dot or space on the face of the CRT. A logical 1 causes a dot and a logical 0 leaves a space. As an example, 16 words of data containing all 1 s displays a row of dots on the face of the CRT. In the Graphic mode, 3200 ( $200 \times 16$ ) words must be defined because there is no way to generate End-of-Screen (EOS). If the full screen is not used, the remainder of the memory locations used should contain all Os.
12.3.2.2 ASCII Decoding ROMs - The ASCII decoding ROMs decode the 7-bit ASCII code from the Line Buffers and generate a video signal for each line of each character to be displayed. After the start of a horizontal scan, data is shifted out of the Line Buffers to address (the buffer is in a recirculating mode, thus an end-around shift) a ROM character generator location and generate video for one line of the character. ROM character generator locations are addressed seven times (once for each horizontal scan). The video signals generated each time it is addressed are changed by the assertion of signals inside the ROM to change the video pattern and produce the desired character after seven scans. The video out of ROM (VIDEO1-VIDEO5) is applied to the Alphanumeric Video Buffer where it is shifted out to the Video Control logic as five serial video pulses. These pulses will cause dots or spaces to appear on the face of the CRT and after seven scans, an alphanumeric character is formed.
12.3.2.3 Graphic Video Buffer - In the Graphic mode, the contents of the Line Buffer are transferred one word at a time to the Graphic Video Buffer. From the Graphic Video Buffer the 12 -bit word is converted to serial video pulses and applied to the Video Control logic. Dots are displayed for data 1 s and spaces for data 0 s .
12.3.2.4 Character Display Mode Detection Logic - The Character Display mode is determined by CB3 and CB4 (Figure 12-7) of the data word from memory. As shown in Figure 12-7, the character may be displayed in the Normal, Blink, Bold, or Cursor modes. The Mode Detection logic decodes CB3 and CB4 to assert the control signals necessary to select the four modes.
12.3.2.5 Visible Field Detection Logic - The visible field is determined by CB1 and CB2 (Figure 12-7) of the data word. As shown in Figure 12-7, the character may be displayed in the mode selected by CB1 and CB2 (NOP), a
blank field may be ended and the display enabled (EBL), a blank field may be started (BBF) or an End of Screen (EOS) may be selected to end the display. EOS is particularly helpful because it allows smaller displays to be displayed without using the entire core buffer. This saves core buffer space and reduces processor loading.
12.3.2.6 Single Cycle Data Break Control Logic - The Single Cycle Data Break Control logic is used to force the processor into the Direct Memory Access (DMA) state and transfer data between core memory and the VT8-E Line Buffers via the Memory Data lines. Memory is addressed by the outputs of Starting Address and Extended Starting Address counters which are applied to the Memory Address lines at the beginning of the break cycle.
12.3.2.7 Processor Control Signals - When the processor is forced into the DMA state, the VT8-E must generate control signals to control the processor. The control signals required to accomplish this are shown in Figure 12-3 and explained in Chapter 9 of the Small Computer Handbook - DEC, 1972.
12.3.2.8 Break Counters - The Break Counters are used to count the words in a data transfer. The counters overflow after 32 words are transferred in the 32 character mode or after 64 words are transferred in the 64 character mode to stop data transfers and release the processor.
12.3.2.9 MA and EMA Bus Gates - The MA and EMA Bus Gates apply the contents of the Starting Address Counter and Extended Starting Address Counter to the OMNIBUS MA lines during a data transfer. This allows the selection of a memory field and memory location to be used in a data transfer.
12.3.2.10 Data Bus Gates - The Data Bus gates are enabled when the DPMD instruction is executed by the program to transfer data to the Data Bus. This allows VT8-E registers and buffers to be read into the AC for display or evaluation by the program. To read the Display Buffers and Register with IOT instructions the Maintenance logic must be enabled.
12.3.2.11 Maintenance Enable - The Maintenance logic is enabled by the DPSM instruction. This allows the program to read the VT8-E registers and buffers using the maintenance instructions. It also allows data breaks to be taken by the VT8-E at a rate determined by the program.
12.3.2.12 Frequency Divider Board (M8336) - The functional groups of logic on the M8336 module are discussed in the following paragraphs.
12.3.2.13 Display IOT Decoder - The Display IOT Decoder decodes the Display instructions and generates the necessary control signals to set up for data breaks, maintenance operations, and data transfers using IOT instructions. The decoder is enabled when I/O PAUSE is asserted and the device code assigned to the display for this VT8-E is decoded and decodes bits MD9-MD11 of the IOT instruction. At this time the C lines are asserted to control the direction of the data transfer, INTERNAL I/O is asserted to prevent the processor from performing other IOTs, and the instruction is executed by the VT8-E.

### 12.3.3 VT8-E Clock and Frequency Divider (M8336)

The VT8-E Clock and Frequency Divider generates the necessary CRT sync pulses and control signals required to display data on the CRT. The timing chain consists of a 21.84 MHz crystal controlled oscillator and a chain of divide-by counters with selected outputs used to generate sync and control signals. Jumpers are provided to allow the selection of 64 or 32 character display control signals. These jumpers allow control signals of different frequencies to be selected for the display of 32 or 64 characters per row. The counters in the timing chain and their function are discussed in detail in Paragraph 12.4.2.2.
12.3.3.1 Real Time Clock Flag - The Real Time Clock flag is set (1) at the start of each vertical retrace. If interrupts are enabled, an interrupt request is made, or if a Skip instruction is being executed by the program, the SKIP bus is grounded and the program will skip an instruction.
12.3.3.2 Video and Sync Combining Circuits - The Video and Sync Combining circuits combine the horizontal and vertical sync with the video pulses from the ROM Character Generator to produce a composite video signal.

### 12.3.4 IOT Instructions

The following instructions are used to program the VT8-E.
12.3.4.1 Display Instructions - The Display instructions assume device code 05 is used. There are 64 possible device codes which can be used (Table 12-2) for the display. The device code for the display, keyboard, and printer must be different (e.g., device code 03 for the keyboard, 04 for the printer, and 05 for the display). If more than one VT8-E is installed in the same system, three new device codes must be selected for the second VT8-E. They must also be different from each other and different from the device codes assigned to other PDP-8/E options installed in the system.

## Load Starting Address Register (DPLA)

Octal Code: 6050

Operation: Transfer the contents of the AC to the Starting Address Register (SAR) and clear the AC. The AC must contain the address of the first memory location to be used in a data transfer. The contents of the SAR are transferred to the Address Counters and incremented at the end of each Single Cycle Data Break. This allows the sequential selection of locations in memory for data transfers.

Load Extended Starting Address (DPGO)
Octal Code: 6051
Operation: Transfer the contents of AC10 and AC11 to the Mode Select logic, and AC6-AC8 to the Extended Starting Address Register (XSAR). AC10 and AC1 1 are used to select Alphanumeric or Graphic mode and enable or disable the interrupt system as follows:

| 0 | 0 | Alphanumeric Mode, Interrupt Disabled |
| :--- | :--- | :--- |
| 0 | 1 | Alphanumeric Mode, Interrupt Enabled |
| 1 | 0 | Graphic Mode, Interrupt Disabled |
| 1 | 1 | Graphic Mode, Interrupt Enabled |

AC6-AC8 must contain the memory field to be used in a data transfer. The XSAR Register is incremented when the SAR overflows at the end of each memory field to select the next memory field. The SAR selects the first location (0000) in the new memory field. Data transfers may start immediately after this instruction is executed.

STOP the Display (DPSM)

Octal Code: 6052
Operation: STOP the display and inhibit video and VT8-E initiated data breaks. This instruction also transfers AC11 and AC6-AC8 from the AC to the Maintenance logic and the Extended Starting Address Register. If AC11 is 1 , the Extended Address Register is loaded with the contents of AC6-AC8. If AC11 is 0 , the contents of the Starting Address Register are transferred to the Address Counters and the VT8-E is set up for a maintenance break. The AC must contain the memory field in AC6-AC8 and AC11 must be 1 or 0 to determine which operations are to be done before this instruction is executed.

## Maintenance Instruction (DPMB)

Octal Code: 6053
Operation: Transfer the contents of the memory location specified by the Address Counter to the Data Buffer. The Address Counter is incremented by 1 to select the next location in memory.

## Maintenance Instruction (DPMD)

## Octal Code: 6054

Operation: Jam-transfer the contents of the Data Buffer to the AC. Note that the DPMB and DPMS may be used to transfer data from memory to the Data Buffer and then to the AC where it is displayed. This could aid in troubleshooting the VT8-E.

## Maintenance Instruction (DPMS)

Octal Code: 6055
Operation: Transfer the contents of the Extended Address Counter to AC6-AC8 and the state of the SENSE switch into ACO (Figure 12-4). This allows the program to determine what memory field is selected and determine the condition of the SENSE switch. Bit 0 is a logical 1 when the SENSE switch is on and a logical 0 when the SENSE switch is off. This switch is located on the keyboard and the programmer determines its use and meaning.

Figure 12-4 Extended Address and Sense Switch Data

## Skip On Real Time Clock Flag (DPCL)

Octal Code: 6056
Operation: Skip the next instruction if the Real Time Clock flag is set (1) and clear the flag. Real Time Clock flag is set at the start of each vertical retrace.

Generate A Bell Tone (DPBL)

Octal Code: 6057
Operation: Generate a half-second audible tone for use as a bell. This tone can be heard by the operator and can be used to alert the operator that he must respond; i.e., supply data to the program via the keyboard.
12.3.4.2 Keyboard Instructions - The keyboard instructions assume a device code of 03 has been selected for the keyboard.

Octal Code: 6030

Operation: Clear the Keyboard flag. The Keyboard flag is set when the Keyboard transmitter is ready to transfer data, usually after one of the keyboard keys has been pressed.

## Skip on Keyboard Flag (DKSF)

Octal Code: 6031
Operation: Skip the next sequential instruction if Keyboard flag is set. Keyboard flag sets when one of the keyboard keys has been pressed to supply data to the program.

## Clear Keyboard Flag and AC (DKCC)

Octal Code: 6032
Operation: Clear the Keyboard flag and the AC.
Logically OR Keyboard Buffer and the AC (DKOB)
Octal Code: 6034
Operation: Logically OR the contents of the Keyboard Buffer with AC5-AC11, deposit the result in AC5-AC11, and transfer a 1 to AC4. AC0-AC03 remain unchanged. When DKOB is combined with the CLA instruction, the contents of the Keyboard Buffer are transferred to AC5-AC11.

## Enable Keyboard Printer Interrupt (DKIN)

Octal Code: 6035
Operation: Enable Keyboard Printer interrupt if $\mathrm{AC} 11=1$ or disable if $\mathrm{AC} 11=0$. AC11 must be set to 1 or $\mathbf{0}$ before this instruction is executed by the program.

## Read Keyboard Buffer (DKRB)

Octal Code: 6036
Operation: Jam-transfer the contents of the Keyboard Buffer to AC5-AC11 (Figure 12-5), set AC4 to 1, clear AC0-AC3, and clear the Keyboard flag. AC5-AC6 contains a 7-bit ASClI code which represents the key pressed on the keyboard.

Figure 12-5 Keyboard Data Format
12.3.4.3 Printer Instructions - The following instructions assume a device code of 04 is used for the printer.

Set Printer Flag (PNSF)

Octal Code: 6040

Operation: Set the Printer flag
Skip on Print Done Flag (PNSK)
Octal Code: 6041

Operation: Skip the next sequential instruction if the Print DONE flag is set.
Clear Printer Flag (PNCF)

Octal Code: 6042

Operation: Clear the Printer flag.
NOTE
Octal Code 6043 is not used.

Load Printer Buffer (PNLP)
Octal Code: 6044

Operation: Load the Printer Buffer from AC5-AC11 (Figure 12-6) and Print. AC5-AC11 contains a 7-bit ASClI code which determines the character to be printed.

Figure 12-6 Printer Data Format

Skip on Keyboard or Printer Interrupt (PNSI)
Octal Code: 6045
Operation: Skip if the interrupt is enabled and either the Keyboard or Print DONE flag is set.
Load Printer Buffer (PNPC)
Octal Code: 6046

Operation: Load Printer Buffer from AC5-AC11 (Figure 12-6), Clear Print DONE flag, and Print. The 7-bit ASCII code determines the character to be printed.

### 12.3.5 Display Data Format

The two types of data that can be displayed on the VT8-E CRT are alphanumeric and graphic data.
12.3.5.1 Alphanumeric Data Format - Alphanumeric data displayed on the CRT is determined by the 12 -bit word (Figure 12-7) transferred from memory during a Single Cycle Data Break. This word determines the visible field, character display mode, and the character to be displayed as shown in Figure 12-6. The VT8-E can display 20 lines of alphanumeric information; 64 normal sized characters or 32 enlarged characters can be displayed on each line.

NOTE
EOS allows termination of the display and LF code 012 allows termination of the current row. Both termination methods save core memory and computer time for display with less than 20 lines.

Figure 12-7 Alphanumeric Display Data Format
12.3.5.2 Graphic Data Format - The VT8-E is capable of displaying graphic information on a 189 (width) $\times 200$ (height) dot matrix. Each dot position corresponds to a bit of a data word in the core buffer. The first word of the buffer defines the first 12 dots on the first row. Bit 0 is the first to be displayed and bit 11 the last. If a bit is set to 1 , a dot is displayed and if it is set to 0 , no dot is displayed. Sixteen 12 -bit words are required to display one line of graphic data. The last 3 bits of the sixteenth word are not used. As an example, 16 words of all 1 s (7777) from memory would cause a line of 189 dots to be displayed on the face of the CRT. In the Graphic mode there is no way to terminate the buffer short of 3200 words ( 200 lines), thus the entire buffer must be defined even if a major portion is blank.

### 12.3.6 Display Monitor and Keyboard Switches and Controls

12.3.6.1 Display Monitor Switches and Controls - Table 12-4 lists the switches and controls found on the Display Monitor enclosure.

Table 12-4
Switches and Controls

| Control/Switch | Location | Function |
| :---: | :---: | :---: |
| CONTRAST Control | Right-hand side | Used to adjust the picture for contrast. |
| BRIGHTNESS Control | Right-hand side | Used to adjust the CRT brightness (intensity). |
| VERTICAL Control | Right-hand side | Used to synchronize the raster in the vertical direction. |
| HORIZONTAL Control | Right-hand side | Used to synchronize the raster in the horizontal direction. |
| ON/OFF Switch | Keyboard upperright corner | Applies primary power when in the ON position. |
| $115 \mathrm{~V} / 230 \mathrm{~V}$ | Right-hand side of CRT frame | Selects 115 V or 230 V as primary power for the display. |
| AC Circuit Breaker pushbutton | Rear panel | Resets circuit breaker after momentary fault (do not hold in). |
| SENSE switch | Right-hand side | Use determined by the programmer $\begin{aligned} & \text { ON = logical } 1 \\ & \text { OFF = logical } 0 \end{aligned}$ |

12.3.6.2 Keyboard Controls - The basic function of the Keyboard is to provide a convenient, on-line method of transmitting ASCII-coded characters to the CPU for processing and, perhaps, display on the VT8-E CRT screen. The keyboard transmits an ASCII code directly to the computer each time a key is pressed, and the computer, in turn may transmit the character code to the VT8-E Control Logic. The Control Logic determines if the received data is to be displayed or used to control the displayed text format.

The keyboard can transmit either full ASCII or a 97 -character subset. The selected code is determined by an internal selector switch. With the switch set to position 1, the keyboard transmits the full ASCII character set listed in Table 12-5. With the internal switch set to position 2, the keyboard transmits the 97 -character ASCII subset listed in Table 12-6.

The VT8-E Display Monitor does not display lower case alphabetical characters. However, it crn receive both upper and lower case characters, which are interpreted and displayed as upper case characters (Table 12-7).

Table 12-5

| VT8-E Transmit Codes - Full ASCII Operation |  |  |  |  |  |  |  |  |

### 12.3.7 Programming Examples

The following VT8-E programming examples are programs that may be used to display alphanumeric or graphic data on the CRT.
12.3.7.1 Graphic Display Program Example - This program displays data from the Switch Register in a $189 \times 200$ dot matrix. A dot is displayed for those bits on the Switch Register that are set to 1 s and a space is displayed for those bits in the Switch Register that are set to 0 .

| Memory <br> Location | Instruction | Mnemonic |  |  | Operation |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0200 | 6007 | VTGRPH, | CAF |  | /CLEAR AND INITIALIZE, |
| 0201 | 1216 |  | TAD | BUF | /LOAD THE STARTING ADDRESS |
| 0202 | 6050 |  | DPLA |  | /OF THE DISPLAY BUFFER INTO THE VT8-E. |
| 0203 | 1221 |  | TAD | K2 | /CODE FOR GRAPHIC |
| 0204 | 6051 |  | DPGO |  | /DISPLAY IN GRAPHIC MODE. |
| 0205 | 1217 | VT, | TAD | BUFM1 | /SET AUTO INDEX FOR STORING |
| 0206 | 3010 |  | DCA | 10 | /THE DATA IN THE SR. |
| 0207 | 1222 |  | TAD | M6200 | /LENGTH OF DISPLAY BUFFER |
| 0210 | 3220 |  | DCA | COUNT | /SET COUNTER FOR FILLING BUFFER. |
| 0211 | 7604 |  | LAS |  | /READ DATA PATTERN FROM THE SR. |
| 0212 | 3410 |  | DCA 1 | 10 | /STORE IN BUFFER |
| 0213 | 2220 |  | ISZ | COUNT | /BUFFER FILLED. |
| 0214 | 5211 |  | JMP | .-3 | /NO, CONTINUE FILLING IT. |
| 0215 | 5205 |  | JMP | VT | /RELOAD BUFFER AGAIN. |
| 0216 | 0400 | BUF, | 400 |  | /STARTING ADDRESS OF BUFFER. |
| 0217 | 0377 | BUFM1, | 400-1 |  | /STARTING ADDRESS OF BUFFER-1. |
| 0220 | 0000 | COUNT, | 0 |  | /COUNTER FOR FILLING BUFFER. |
| 0221 | 0002 | K2, | 2 |  | /GRAPHIC ENABLE WORD. |
| 0222 | 1600 | M6200, | -6200 |  | /COUNT FOR FILLING BUFFER. |

\$
12.3.7.2 Alphanumeric Display Program Example - This program echos the character typed on the console keyboard on the VT8-E display. The Switch Register is ORed with the character to display the character in the Normal, Blink, Bright, or Cursor mode. The display mode is selected from the Switch Register (Figure 12-7) as follows:

| 0000 | Normal |
| :--- | :--- |
| 0200 | Blink |
| 0400 | Bright |
| 0600 | Cursor |

| Memory |  |  |  |  |  |

| 0240 | 5400 | M2400, | -2400 |  | /LENGTH OF BUFFER. |

## SECTION 4 DETAILED LOGIC DESCRIPTION

### 12.4 INTRODUCTION

A simple block diagram of the VT8-E Video Display and Control is shown in Figure 12-8. The interface supplies the monitor with video and sync signals, and an audio tone. The video is either alphanumeric character information or graphic information, or a combination of the two that is made possible by switching the display mode at the screen refresh rate.

Figure 12-8 VT8-E Functional Block Diagram

The keyboard transfers data directly to the computer's AC Register by program interrupts or flags. Each character code transmitted can either be displayed or used to control the displayed text format. Data transmitted to the system printer is also transferred by program interrupts or flags. When the Interrupt System is disabled, flags are checked by the SKIP instructions.

The logic description is divided into two parts: one part concentrates on the interface logic for both the keyboard/printer and the display, while the second part concentrates on the keyboard and CRT circuits.

### 12.4.1 Keyboard/Printer Logic

A block diagram of the VT8-E Keyboard/Printer logic is shown in Figure 12-9. Pin assignments for OMNIBUS signals and connector signals can be found on Engineering Drawing E-CS-M8335-0-1.

Figure 12-9 Printer/Keyboard Block Diagram

The VT8-E Keyboard/Printer logic has two distinct functions: transfer of data from the CPU AC Register to the Printer Buffer Register and transfer of data from the Keyboard Register to the AC Register. The transfer of data to the Printer Buffer is carried out by the Printer Receive logic. When the printer is able to receive data, it asserts the DEMAND signal. This signal sets the PRNT FLG flip-flop in the Printer Receive logic. The resulting PRNT (0) L signal causes the INT/SKIP logic to assert the OMNIBUS INT ROST L signal, if the VT8-E has been logically connected to the interrupt system. Alternatively, PRNT ( 0 ) $L$ can be tested by a program skip instruction in the INT/SKIP logic. In either case, the computer ultimately proceeds to a program subroutine that begins the data transfer. When this subroutine is executed, the information is transferred from the AC Register to the DATA 5-11 lines and clocked into a 7 -bit register in the Printer Receive logic. The register outputs are available at J 1 as the BIT 1-7 signals. The logic then generates a PRINTER STROBE L signal that clocks the BIT $1-7$ data into the Printer Buffer Register, clears the PRNT FLG flip-flop, and caises the printer to negate the DEMAND signal.

The transfer of data from the Keyboard Buffer Register to the AC Register is carried out by the Keyboard Transmit logic. When a keyboard key is pressed, information is applied, via the BIT 1-7 lines, to a 7 -bit register in the Keyboard Transmit logic. When the keyboard generates a KEYBOARD STROBE L signal, the information is clocked into the 7 -bit register and the KYBD FLG flip-flop is set. The KYBD ( 0 ) L signal can be tested in the INT/SKIP logic with a SKIP instruction, or the interrupt system can be used to cause the program to enter an appropriate subroutine. When the subroutine is executed, the information is gated from the register in the Keyboard Transmit logic to lines DATA 5-11 (the logic asserts the DATA 4 L signal separately so that the input character is compatible with the modified-ASCII Teletype code), then to the AC Register. The AC is loaded and, simultaneously, the KYBD FLG flip-flop is cleared.
12.4.1.1 IOT Decoder Logic - The IOT Decoder logic is shown in Figure 12-10, which includes the Video Display Decoding logic for reference. The VT8-E Keyboard/Printer uses 12 IOT instructions, 6 for the keyboard and 6 for the printer. (One of the listed printer IOTs, Skip on Printer or Keyboard Interrupt, apply to both functions and one of the keyboard IOTs, Interrupt Enable/Disable.) More than one keyboard/printer can be interfaced to the PDP-8/E at the same time. The VT8-E (or other control module) associated with each keyboard/printer must be assigned a unique device selection code for both the keyboard and the printer. Therefore, the M8335 module is fabricated with jumpers and solder terminals that allow the user to assign any one of 64 possible device selection codes to both the keyboard and the printer (care should be taken when assigning device selection codes to preclude multiple assignments of the same code). Figure 12-10 illustrates the octal codes and mnemonics that pertain when the VT8-E is manufactured. The octal codes and mnemonics for the instructions are listed in Paragraph 12.3.2. A complete list of device codes and the jumpers required to select each device code is shown in Table 12-2.
12.4.1.2 Printer Receive Logic - The Printer Receive logic is shown in Figure 12-11. Significant signals are related by the timing diagram in Figure 12-12. Refer to both figures when reading the logic description.

The printer routine is initiated by DEMAND changing to the true state, indicating that the printer is ready for another character. This sets the PRNT flag flip-flop. This flip-flop can also be set by the PNSF instruction at TP3 time. If the VT8-E is logically connected to the interrupt system, as this discussion assumes, the PRNT FLG (1) L signal causes the INT/SKIP logic to assert the OMNIBUS INT ROST L signal. The program proceeds to an interrupt servicing routine to determine the identity of the requesting device. The PNSI instruction in the routine causes the program to jump to a VT8-E routine that determines whether the printer or keyboard requested the interrupt (other options are open to the programmer, this is but one example). Ultimately, the VT8-E printer routine executes the PNPC instruction.

During TS2 of the PNPC instruction, information is gated from the AC Register to the DATA lines and remains on the DATA lines through TS3. When PNPC $L$ is decoded in the IOT Decoder logic, it enables NOR gates E25C and E25D (Figure 12-11). NOR gate E25-D asserts the DATA EN signal; both DATA EN A L and DATA EN B L are derived from this signal. The difference between the DATA EN A L and DATA EN B L signals is significant only when considering the Display logic; for the present one must know only that one of these two signals gates lines DATA 9 and DATA 10 to the 7 -bit register. The remaining DATA lines are gated to the register flip-flops as shown.

Figure 12-10 IOT Decoder Logic

Figure 12-11 Printer Receive Logic

At TP3 time of the instruction, NAND gate E-17 is enabled and the information on the DATA lines is clocked into the 7-bit register. Simultaneously, flip-flop STROBE 1 sets and the PRNT FLG flip-flop is cleared. The register data is applied, via the BIT 1-7 lines, to the Printer Buffer Register. At the beginning of TS2 of the instruction following PNPC, flip-flop STROBE 2 sets and asserts PRINTER STROBE L. This signal loads the Printer Buffer Register and negates the DEMAND signal. Both STROBE 1 and STROBE 2 are cleared by the next TP3. When the print cycle ends approximately 30 ms later, the DEMAND signal is again asserted and a new transfer can be started.

Figure 12-12 Printer Receive Logic Timing
12.4.1.3 Keyboard Transmit Logic - The Keyboard Transmit logic is shown in Figure 12-13. Significant signals are related by the timing diagram in Figure 12-14. Refer to both figures when reading the logic description.

Figure 12-13 Keyboard Transmit Logic

Figure 12-14 Keyboard Transmit Logic Timing

The user initiates the keyboard sequence by pressing a key on the keyboard. The character information is placed on the BIT 1-7 lines. After a period of time that allows the BIT lines to settle, the keyboard generates the KEYBOARD STROBE H signal. The trailing edge of this signal clocks the information into the 7 -bit register and sets the KYBD FLG flip-flop. If the VT8-E is logically connected to the interrupt system, as assumed, the KYBD FLG (1) L signal causes the INT/SKIP logic to assert the OMNIBUS INT ROST L signal. The program proceeds to an interrupt servicing routine to determine the identity of the requesting device. The PNSI instruction in the routine causes the program to jump to a VT8-E routine that determines if the printer or keyboard requested the interrupt. Ultimately, the VT8-E keyboard routine executes the DKRB instruction.

When the DKRB instruction is decoded, the IOT Decoder logic generates the DKRB $L$ signal and activates the OMNIBUS C0 and C1 lines. The DKRB L signal enables NOR gates E17C and E17D; the output signal from E17D gates the information from the register outputs to DATA lines 5-11, and also causes NAND gate E27 to assert the DATA 4 L signal. The DATA lines are gated to the AC Register and the information is clocked into the register at TP3 time. Also at TP3, the KYBD FLG flip-flop is cleared, readying the logic for a new data transfer.
12.4.1.4 INT/SKIP Logic - The INT/SKIP logic is shown in Figure 12-15. The PRNT FLG (1) L signal and the KYBD FLG (1) L signal can cause program skips when tested by instructions PNSK and DKSK, respectively. The signals can also be tested by the PNSI instruction, provided the ENA flip-flop, E37, has been set, logically connecting the VT8-E to the interrupt system. When E37 is set, the PNSI L signal enables NAND gate E29, which, in turn, enables NAND gate E34, if either the PRNT FLG (1) L signal or the KYBD FLG (1) L signal is asserted. Simultaneously, NAND gate E13 asserts the INT ROST L signal.

Figure 12-15 Keyboard/Print Interrupt and Skip Logic

The ENA flip-flop is set by the OMNIBUS INIT signal for the PDP-8 family computers. To clear the flip-flop, remove the VT8-E from the interrupt system, load AC11 with logic 0 and then program the DKIN instruction. The logic 0 in AC11 keeps the DATA 11 L signal negated. Thus, the $D$ input of $E 37$ remains high. At TP3 time, NAND gate E22B provides a clock pulse for E37, clearing the flip-flop. E37 can be set at any time with the same instruction merely by loading AC11 with logic 1.

### 12.4.2 Display Logic

Information displayed by the VT8-E is transferred by data breaks from the PDP-8/E memory. As with all data break devices, the start of the data transfer is under program control. However, the VT8-E is a 1 -cycle data break device; consequently, it needs only a starting memory address to carry out the complete data transfer. The starting address, i.e., the memory address of the first data word to be transferred to the VT8-E, is placed in the AC Register by a program TAD instruction. Program IOT instructions gate this address onto the OMNIBUS DATA lines and cause it to be loaded into a starting address register in the VT8-E (Figure 12-16). At the same time, the VT8-E Data Break logic is readied for triggering.

When the CRT sweep is in a specified position, a synchronizing signal is generated by the VT8-E Timing logic. This signal enables the Data Break logic to request a data break and check priority. If no higher priority device has requested a break at this time, the Data Break logic asserts a number of OMNIBUS control signals, enabling direct communication between the interface and memory for one PDP-8/E timing cycle. At the same time, other Data Break logic signals gate the starting address onto the OMNIBUS MA lines. During the data break timing cycle, the data word in the addressed memory location is transferred on the MD lines and loaded into the interface Line Buffer Register. At TP4 time of the timing cycle, the Data Break logic increments the address in the Address Counter. The data word in this new address is transferred during the next data break timing cycle, which might occur immediately after the first (priority is checked during TS4 of each data break cycle; a higher priority device can interrupt the VT8-E data breaks).
After each transfer, the address in the Address Counter is incremented, and the data word in the new address is loaded into the Line Buffer Register. This register holds 32 or 64 data words, depending on the mode (graphic or alphanumeric) or the desired number of alphanumeric characters per line. The Data Break logic counts the number of data breaks; when the specified number of data words has been loaded into the Line Buffer Register, the Data Break logic ceases to request breaks.

Figure 12-16 Display Logic Block Diagram

If the VT8-E logic has been programmed to display 32 alphanumeric characters per line; for example, each data word in the Line Buffer Register contains: the 7-bit ASCII code representation of an alphanumeric character (bits $5-11$ ); data that controls how the character is displayed (bits 3 and 4); and data that controls the visible field (bits 1 and 2). Because the VT8-E displays only a 64-character set, bits 6-11 of the Line Buffer Register contain sufficient data to display all alphanumeric characters. Characters are formed on the CRT screen when the CRT video circuits selectively intensify points within a $5 \times 7$ dot matrix. The letter $F$ is illustrated in Figure 12-17. Each horizontal scan line corresponds to one row of the letter. As the sweep scans along a line, video signals selectively intensify points as illustrated ( 5 video signals in row 1 of the letter F). If 32 alphanumeric characters per line are to be displayed, for example, row 1 of each character is swept out by the same scan line. The next scan line sweeps out row 2 of all 32 characters, and so on until the 7 th scan line sweeps out row 7 of the characters, completing the character line.

Figure 12-17 Video Presentation for the Letter F

The video signals are generated, indirectly, by a ROM Character Generator. After the start of a horizontal scan line, a 6-bit ASCII character is shifted from the Line Buffer Register (at this time, the register is in the recirculating mode; hence, an end-around shift is performed). The character addresses a ROM Character Generator location. This location contains the video information for one row of the character. For example, assume that the letter $F$ is the first character to be displayed in a particular character line. The 6-bit ASCII representation of the letter $\mathbf{F}$ addresses a particular ROM Character Generator location. The information in this location causes row 1 of the letter to be painted during this scan line. The next character to be displayed is shifted from the Line Buffer Register and addresses its unique ROM Character Generator location; the information in the location causes row 1 of this character to be displayed just after character F . Row 1 of all 32 characters is displayed during this scan line.

After the start of the next horizontal scan line, the 6-bit ASCII representation of the letter $\mathbf{F}$ is again shifted from the Line Buffer Register. Meanwhile, certain ROM control signals have been asserted so that the addressed location differs from that of the first scan line. This location contains information that causes Row 2 of the letter $F$ to be painted during this scan line. Row 2 of all other characters is displayed during this scan line in similar fashion. Consequently, the Line Buffer Register is shifted 32 times during each scan line; after 7 end-around shifts of the register, a character line has been displayed.

Each character line comprises ten scan lines, rather than the seven just described. The three additional lines occur at the beginning of the character line. During the first two scan lines, the Line Buffer Register is loaded from the OMNIBUS MD lines; during the third scan line, a blank ROM location is addressed. Figure 12-18 represents two character lines as they would appear on the CRT screen. Character line spacing ( $43 \%$ of character height) is provided by the three blank scan lines.

If the VT8-E has been programmed for a graphic display, one line of graphic data is displayed during each horizontal scan line. A line of graphic data is represented by 1612 -bit data words; each bit of a data word represents a dot or a
space on the CRT screen. The Line Buffer Register is loaded with two lines of graphic data by 32 data breaks. As the sweep scans along a line, video signals selectively intensify points to paint the graphic symbol. Although 16 12-bit data words contain 192 bits, only 189 points can be painted by each scan.

Figure 12-18 Two Alphanumeric Characters Displayed on the CRT
12.4.2.1 VT8-E Timing - The VT8-E Timing logic generates signals that sync the Display logic and the CRT sweep circuits. Figure 12-19 illustrates the CRT vertical and horizontal sweep signals and the VT8-E sync signals.

For 60 Hz operation, the VT8-E timing generates a V SYNC L signal every 16.7 ms . This sync signal causes a vertical retrace, which is carried out in approximately 20 scan lines. A VZONE flip-flop in the timing controls the displayable area in the vertical direction. When the flip-flop is set, the VZONE (1) signal enables a vertical display of 200 scan lines (the horizontal sweep rate is set at 15.6 kHz ; a total of 60 scan lines is made non-displayable to remove distortion-prone areas on the CRT screen).

The timing generates an HSYNC signal every $64.1 \mu \mathrm{~s}$. A HZONE flip-flop in the timing controls the displayable area in the horizontal direction. When the flip-flop is set, the HZONE (1) signal enables graphic or alphanumeric video to be painted in the distortion-free area of the screen (exceptions to this statement are pointed out in the detailed logic discussion).

Figure 12-19 Sweep and Sync Signals

The VT8-E timing is such that either 50 or 100 alphanumeric characters could be displayed between HSYNC signals. The HZONE (1) signal reduces the number of characters to either 32 or 64 , respectively (an equal number of characters is removed on both sides of the screen). Note that the HZONE (1) signal is of shorter duration for the graphic display. This is explained as follows. Clock pulses of the same basic frequency are used to shift the Alphanumeric Video Buffer Register and the Graphic Video Buffer Register. Seven shift signals are needed to display the rows of the $5 \times 7$ alphanumeric character matrix (five signals intensify the scan, two signals provide spacing between each character). Thus, $7 \times 32$, or 224 shift pulses are needed for an entire character line. An entire graphic line needs only 192 shift pulses. Consequently, it seems that the HZONE (1) signal should be reduced by an amount that allows 192 shift pulses to be generated (if the display area is not shortened, an improper display will result). This would mean reducing the graphic displayable area by an amount equal to 32 shift pulses. However, this is not a multiple of seven, which it must be to enable correct alphanumeric display. The closest number that is a multiple of 7 is 35 . Thus, the horizontal zone for graphics allows only 189 shift pulses to be produced, cutting off the last 3 data bits in each scan line (note that 28 could not be used because then too many graphic shift pulses would be produced). The pulses are derived from a 5.46 MHz clock ( $\mathrm{t}=183.15 \mathrm{~ns}$ ). Therefore, 189 shift pulses require an HZONE (1) signal of only $34.61 \mu \mathrm{~s}$.
12.4.2.2 VT8-E Timing Logic - The VT8-E Timing logic generates the CRT sync pulses and the interface control signals. All timing and control signals are derived from a crystal-controlled transistor oscillator that produces pulses at a frequency of 21.84 MHz . These pulses are applied to a Clock Pulse Generator, shown in Figure 12-20. The generator divides the basic frequency by 2 and 4 , producing well-shaped clock pulses of 10.92 MHz and 5.46 MHz . Two test points are available which allow the oscillator clock to be inhibited and external clocks injected to drive the timing chain.

Figure 12-20 Clock Pulse Generator

The clock pulses selected are applied to a chain of DEC 741614 -Bit Counters that counts down the pulse frequency to 3.75 Hz (for 60 Hz operation). Selected outputs of the timing chain are gated to produce sync pulses and control signals.

A logic block representation of the DEC 74161 4-Bit Counter Integrated Circuit (IC) is shown in Figure 12-21. This IC, E17, is the first one in the timing chain. Because it is a 4 -bit counter, E17 can produce one pulse at its CARRY output for each 16 pulses at its COUNT UP input. However, because the IC can be preset to any count, it can produce a CARRY output for any number of input pulses less than 16. The preset inputs are labeled $A$ through $D$ in Figure 12-21 (A is the LSB). They are wired so that E17 is preset with a count of $1001_{2}$ whenever a signal is applied to the LOAD input and a clock pulse occurs. The CARRY signal is generated when the count is in the $1111_{2}$ state and ENP and ENT are true. A Load signal is generated by the OR gate and E17 is preset to $1001_{2}$. Seven more pulses at the clock input produce another CARRY signal and, again, the counter is preset. Thus, the counter divides by seven. The counter can also be preset by a REMOTE V SYNC IN L signal, enabling the timing to be controlled by some external device. The output of each bit, designated QA through QD (QA is the LSB), is available for gating to generate the sync and control signals.

Figure 12-21 4-Bit Counter

Figure 12-22 shows the entire chain of 74161 ICs. Each IC in the figure is represented in shorthand form: i.e., the wiring of the PRESET inputs is not shown, the LOAD input circuits are not shown, and the destination of each output is now shown (only those output bits that are used are indicated on the ICs). The binary designations above each IC block represent the way the preset inputs are wired. For example, E16 is wired thus: PRESET input D is tied to $+3 V$; PRESET input $C$ is grounded; PRESET inputs $B$ and $A$ are tied to $+3 V$. Therefore, $E 16$ is preset with a count of $1011_{2}$ and divides by 5 .

* COUNTER IS PRESET TO THIS 8INARY VALUE

NOTE:

Figure 12-22 VT8-E Timing Chain

Each IC has a NOR gate at its LOAD input, exactly as shown in Figure 12-21; this gate ORs the CARRY output with REMOTE V SYNC and INIT (E17, E12, E16), or with REMOTE V SYNC and 50 Hz RESET (E18, E19, E8, E9). The bit output destinations are shown, in part, only for ICs E19, E8, and E9.

The table in Figure 12-22 indicates the frequency of the CARRY output pulses of each IC. The output frequency from E17 differs for 32 character/line and 64 character/line operation. The bit output signals from E17 determine the alphanumeric character rate, the rate at which characters are painted on the CRT screen. Thus, the rate is twice as fast for 64 character/line operation. E12 divides by two; therefore, the input of E16 is the same for both character rates.

When a 50 Hz line is used, the timing is modified in the last three ICs. For 60 Hz operation, E9 is preset with a count of $0011_{2}$ and its CARRY output provides the LOAD input for E9. E8 and E9, together, divide the output of E19 by 26, producing a CARRY output pulse from E9 at a frequency of 60 Hz . This output is gated elsewhere in the logic to generate the V SYNC L signal that causes a CRT vertical retrace. For 50 Hz operation, the 50 Hz jumpers are connected, and E9 is preset with a count of $0010_{2}$. Furthermore, the LOAD input of E9 is controlled by REMOTE $V$ SYNC IN or 50 Hz RESET H . When E9 attains a count of $001_{2}$ and both E19-D and E8-A are high, E9 is preset and a V SYNC pulse is generated. E8 and E9, together, divide the output of E19 by 31.2, producing pulses having a frequency of 50 Hz . The table shows the output of E9 as 50 Hz (the output is not actually from E9, as for 60 Hz operation, but it is convenient to think of it as sol. As for 60 Hz operation, the output is gated to generate the $V$ SYNC L signal.

Note that the REMOTE V SYNC IN or 50 Hz RESET line is activated when E9 is preset; thus, ICs E18, E19, E8, and E9 are preset at the moment of vertical retrace. This active step is not necessary during 60 Hz operation because all ICs automatically overflow to the preset state.

Figure 12-23 shows the logic that generates the horizontal and vertical sync signals, while Figure 12-24 shows the HZONE and VZONE flip-flops and those signals that control the two flip-flops. The timing diagram in Figure 12-25 shows the line timing for both alphanumeric and graphic display. Two hundred of the HZONE (1) signals are generated for each VZONE signal, as shown in Figure 12-19.

Figure 12-23 Horizontal and Vertical Sync Circuits

Figure 12-24 Horizontal and Vertical Zone Flip-Flops
12.4.2.3 Starting Address Register Logic - The Starting Address Register logic is shown in Figure 12-26. The logic includes two Starting Address Registers: one is a 12-bit register comprised of two DEC 74174 ICs (hex flip-flop); the other uses three bits of a DEC 74175 IC (quad flip-flop). The Address Counter is comprised of four DEC 74193 ICs (4-bit up-counters) connected in series and is preset from the Buffer Registers.

The control signals that load and clock the Starting Address Registers and the Address Counter are generated by the Starting Address Control logic, shown in Figure 12-27. When the program IOT instruction DPLA is issued, the 12-bit starting address is placed on the DATA lines. The DPLA $L$ signal causes both the DATA EN A L and DATA EN B L signals to be asserted. The starting address is gated through the NAND gates to the DEC 74174 inputs and loaded into the buffer at TP3 time by the LD ST ADD signal.

The extended field must also be identified by the EMA bits. The extended field address bits are placed on lines DATA 6, 7, and 8 by the DPGO IOT instruction. The DPGO L signal causes the DATA EN signals to be asserted, gating the extended address to the DEC 74175 inputs. At TP3 time the XST ADD REG is loaded by the LD XST ADD signal (DPGO).

Figure 12-25 Alphanumeric and Graphic Line Timing

The DPGO $L$ signal also clears the MAINT/GO flip-flop (Figure 12-27) at TP3 time, negating the MAINT L signal. This negated signal enables a vertical sweep synchronizing signal, E46(Q), to assert the LD ADD CNTR L signal. This signal loads the starting address (including the extended address) into the 15 -bit Address Counter.

At approximately the same time that the Address Counter is loaded, the Data Break Counting logic is readied for triggering. When the sweep is in the specified position, the COUNTING signal is generated, enabling the Data Break Control logic to request a data break. If the VT8-E has highest priority, the MAC0 and MAC1 flip-flops in the Data Break Control logic are set. The MACO(1) and MAC1(1) signals gate the 15 -bit starting address from the Starting Address Register outputs onto the MAO-11 and EMAO-2 lines. At TP1 of the data break timing cycle, the MAC2 flip-flop in the Data Break Control logic is set. The MAC1(1) signal then enables the Starting Address Control logic to assert the CLK ADD CNTR signal at TP4 time of the data break timing cycle. Thus, the address in the Starting Address Register is counted up by one. The next data break timing cycle transfers the data word in the new address to the VT8-E.
12.4.2.4 Data Break Counting Logic - The Data Break Counting logic is shown in Figure 12-28. This logic generates the COUNTING signal that enables the Data Break Control logic to request data breaks. When the PRESET BRK signal is generated, flip-flop E43A is set, asserting the COUNTING signal. The COUNTING signal enables the NBR flip-flop in the Data Break Control logic to be set at INT STROBE time. If the VT8-E has highest priority, data breaks begin. Each TP1 signal of a data break timing cycle causes NAND gate E42 (Figure 12-28) to assert the COUNT BRK signal. This signal is counted by the 4-bit up-counter, E53. When the correct number of data breaks has been performed, flip-flop E43A is cleared via NOR gate E33 and data breaks cease.

NOTE
Logic is P/O MB335 unless noted.

Figure 12-26 Starting Address Register Logic

NOTE:

Figure 12-27 Starting Address Register Control Logic

Figure 12-28 Data Break Control Logic

If the logic has been programmed for an alphanumeric display (assume 32 characters/line), 32 data words must be loaded into the Line Buffer Register during two scan lines of the character row. During each of the eight remaining scan lines, the Line Buffer Register is recirculated. Thus, new information is loaded once every ten scan lines and the PRESET BRK signal must be generated only once every ten scan lines.

Note that the logic within the dashed line in Figure 12-28 generates the PRESET BRK signal. The VSYNC L signal prepares this logic for triggering by setting flip-flop E43B, thereby asserting the GO AFTER VSYNC signal (the MAINT L signal is negated by the Starting Address Control logic when a DPGO instruction is issued). VSYNC L also clears the 4-bit up-counter and the two J-K flip-flops. When the VZONE flip-flop is set, NAND gate E7 is enabled. Each E19 CARRY signal that occurs causes PRESET BRK to be generated. Because E19 CARRY occurs once every ten scan lines, the Line Buffer Register is loaded once every ten scan lines, as required.

Figure 12-29 illustrates the timing of the counting network for an alphanumeric display of 32 characters/line. This timing applies to a graphic display, as well, although the GRAPH L signal would be asserted for such a display. If the logic has been programmed for a graphic display, the PRESET BRK signal must be generated differently. Sixteen data words are needed to display one line of graphic data. Thus, the Line Buffer Register can hold two lines of graphic data. Since a line of graphic data is displayed by one scan line, a PRESET BRK signal is required once every two scan lines. The logic in Figure $12-30$ is used to generate the Graphic mode PRESET BRK signal. It is similar to the PRESET BRK logic in Figure 12-28. The VSYNC L signal is used in the same way and the data breaks are counted by the counting logic in the same way. The LN CNT signal occurs at the end of each scan line, but the E19-A signal is high for every other scan line. Consequently, the graphic PRESET BRK occurs once every two scan lines.

Figure 12-29 Data Break Counting for 32 Characters/Line

Figure 12-30 PRESET BRK Generation Graphic Mode
12.4.2.5 Data Break Control Logic - The Data Break Control logic is shown in Figure 12-31. When the COUNTING signal is asserted by the Data Break Counting logic, NAND gate E52 is enabled. (MAINT L is negated by the DPGO instruction and HALT BRK L is asserted only for line-feed or end-of-screen.) The NBR flip-flop is set at INT STROBE time, asserting the NBR (1) signal. This signal asserts OMNIBUS signals CPMA DISABLE L and BRK IN PROG L and causes the VT8-E priority to be placed on the DATA lines during TS4. CPMA DISABLE L causes the CPU CPMA Register to be disconnected from the OMNIBUS MA lines, while BRK IN PROG L ensures that only data break devices place priority information on the DATA lines during TS4.

Figure 12-31 Data Break Control Logic

If the VT8- E has highest priority, MY PRIORITY L is asserted by the Priority logic (Figure 12-33). This signal is NANDed with the 0-output of the NBR flip-flop to produce a high logic level at the D-input of both the MACO and MAC1 flip-flops; the flip-flops are set at TP4 time via NAND gate E28. The MACO(1) signal asserts MS, IR DISABLE L, BREAK CYCLE L, and MD DIR L, and enables the MAC2 flip-flop to be set at TP1 time of the data break cycle, thereby asserting MALC L. These OMNIBUS signals complete the CPU takeover process. MS, IR DISABLE L forces the CPU to enter the Direct Memory Access (DMA) state and disables the CPU IR Register. The MALC L signal prevents the CPMA Register from being clocked during the data break operation, while the BRK CYCLE L signal is applied to the programmer's console and can be monitored on the display panel.

The MD DIR $L$ signal is asserted so that the data word transferred during the data break timing cycle is rewritten in the memory location during the write half of the memory timing cycle.

The MAC1 ( 0 ) signal is applied to NOR gate E42 to ensure that MAC0 and MAC1 can be cleared by TP4 whenever NBR is cleared at INT STROBE time. The MAC1 and MAC2 outputs are used as gating signals elsewhere in the Display logic.

Figure 12-32 Data Break Halt, Line Feed/EOS Logic
12.4.2.6 Data Break Halt, Line Feed, and End-of-Screen Logic - The Data Break Halt, Line Feed, and End-of-Screen logic is shown in Figure 12-32. This logic is used to clear the NBR flip-flop and stop Single Cycle Data Breaks as follows:
a. If the line feed ASCII code (012) is detected on the MD lines, E47A sets. This clears NBR if the counter has not overflowed and the Maintenance mode is not enabled.
b. If the Character Counter overflows when 64 or 32 characters are transferred, counting is negated.
c. If the EOS code is detected (Figure 12-7) and EOS CODE $L$ is asserted.
d. If V SYNC L is asserted at the end of the vertical scan.

If NBR is cleared by EOS CODE or LF CODE before the Character Counters have counted 64 or 32 characters, FIN SHIFT (E51) sets. This allows the counters to continue counting until they overflow (read all Os) so that they will contain a 0 count when the next data break is initiated. FIN SHIFT also allows BRK SHIFTS to be generated in order to shift the line buffer data into the correct position. FIN SHIFT is clocked at each TP4 time and will clear at the first TP4 time after COUNTING is negated.

IOT3. MAIN L is used to set NBR to cause one Single Cycle Data Break if the DPMB Maintenance instruction is executed by the program.
12.4.2.7 Priority Logic - The Priority logic is shown in Figure 12-33. Similar logic is contained on all interfaces that connect to the OMNIBUS. Priority is checked during TS4 immediately following the INT STROBE signal that sets the NBR flip-flop.

The VT8-E can have priority 10, 11, or 12. The device having the lowest priority (12) asserts the DATA 11 L signal during TS4. Assume that priority 11 is assigned. This priority causes the VT8-E to assert the DATA 10 L signal during TS4 L (jumper W2 in the Data Break Control logic is connected). Jumpers P10 and P9' must be connected in the Priority logic. Because the DATA EN B L signal is asserted when NBR(1) is high, any data break device with a higher priority can enable one of the NAND gates (the DATA EN A L signal is high throughout the priority check). Thus, MY PRIORITY L is not asserted and VT8-E data breaks do not begin.

If the VT8-E is assigned priority 10, jumpers P10 and P9 are connected. Higher priority devices can assert any of DATA lines 0 through 8, thereby preventing the VT8-E from beginning data breaks. However, any device with a lower priority, 11 or 12 , must wait until the VT8-E relinquishes control of the CPU.
12.4.2.8 Line Buffer Register and Control Signal Logic - The Line Buffer Register logic is shown in Figure 12-34. The register comprises four DEC 2518 ICs (hex 32-bit Shift Registers) and is loaded from the MD lines during each data break cycle [MAC2 (0) is asserted low] by control signals generated in the Line Buffer Register Control logic (Figures 12-35 and 12-36).

If 32 alphanumeric characters are to be displayed, Component Registers B1 and B2 are used as a $12 \times 32$-bit Shift Register that is loaded with the 32 ASCII-coded characters. If 64 characters must be displayed, the A1 and A2 Component Registers are also used as a $12 \times 32$-bit Shift Register. However, the two $12 \times 32$-bit registers are loaded alternately, word by word from the MD lines. Consequently, they function together as a $12 \times 64$-bit Shift Register. If graphic data is displayed, the $A$ and $B$ Registers operate as two independent $12 \times 32$-bit Shift Registers. While one is displaying two scan lines of data, the other is refreshing for the next two scan lines.

When the LD B L signal, for example, is asserted, the $12 \times 32$-bit B Register can be loaded from the MD lines. Data gated to the LOAD inputs is shifted by the CLK B signal. When the LD B L signal is negated, the LOAD inputs are disabled; the CLK B signal produces an end-around shift of the data that has been loaded.

Figure 12-33 Priority Logic

Three DEC 74157 ICs (quad multiplexers) are included in the Line Buffer Register logic. The READ SELECT signal controls the multiplexers, causing either the $A_{n}$ inputs or the $B_{n}$ inputs to be gated to the $f_{n}$ outputs. The outputs are transferred to the Video Buffer logic, alphanumeric or graphic, and converted to serial video information.

Figure 12.37 shows a timing diagram that illustrates how the Line Buffer Register and the multiplexer are controlled when 32 alphanumeric characters are to be displayed. The timing shown is relative; pulse durations, gate widths, etc., may or may not be actual.

Figure 12-34 Line Buffer Register Logic

The period of time represented as $t_{1}$ is that period during which 32 data breaks are being performed (remember that two scan lines are set aside for this purpose). During $\mathrm{t}_{1}$ the Line Buffer Register must be loaded from the MD lines. The Line Buffer Register Control logic (Figure 12-35) asserts the LD B L signal (the signal E19-D is low throughout $t_{1}$, keeping the VIS ZONE $L$ signal high). Each data break cycle causes a data word to be gated to the B Register LOAD inputs. The BRK SHIFT signal that occurs during TS3 L of the break cycle is gated through NAND gate E37A, since the ALPHA CLK ALT is always cleared during a 32 character operation. This causes a CLK B signal to be produced. When 32 data words have been loaded into the register, the COUNTING signal goes low and data breaks cease (COUNTING goes low at TP1 of the break cycle, while BRK SHIFT is asserted during TS3 L).

Figure 12-35 Line Buffer Register Control Logic

Throughout each of the next eight scan lines, the Line Buffer Register must be shifted end-around. Period $\mathrm{t}_{2}$ represents the third scan line and the beginning of the fourth. The VIS ZONE $L$ signal is asserted when HZONE(1) goes high. The LD B L signal is negated, placing the register in the recirculating mode. During the time that VIS ZONE $L$ is low, the VT8-E timing generates 32 SHIFT LINE BUFFER signals. These signals enable NAND gate E37A, thereby generating the CLK B signal. The register is shifted end-around by 32 CLK B signals. (Note that 31 CLK B signals are sufficient to shift all 32 characters through the multiplexer, but 32 are needed for the recirculation.) Each time a character is placed on the register outputs, the multiplexer gates it to the ROM Character logic (only the 6 -bit ASCII code, bits 6-11, is gated to the ROM). There it is converted to serial video information for display.

Figure 12-36 Line Buffer Register

The same operation is performed during each succeeding scan line. At the end of the tenth scan line, the character line has been displayed. Another PRESET BRK signal is generated and 32 more characters are loaded into the Line Buffer Register. Note that as these next 32 characters are shifted into the register, the 32 displayed by the just-completed character line are shifted out. Because video is not enabled unless VIS ZONE $L$ is low, there is no danger of these earlier characters being displayed again.

Figure $12-38$ shows a timing diagram that illustrates how the Line Buffer Register and the multiplexer are controlled when 64 alphanumeric characters are loaded from the MD lines. Both the $A$ and $B$ Registers are used, providing 64 bits of storage space. As the timing diagram illustrates, the $A$ and $B$ Registers are loaded alternately so that each contains 32 characters when 64 data breaks have been completed. The registers are alternately recirculated during each succeeding scan line (this timing is not shown, but is similar to that of Figure 12-37); when the characters have been displayed, 64 new characters are shifted into the register.

Figure 12-36 shows the logic that controls the Line Buffer Register and the multiplexer during a graphic display. Figure $12-39$ shows a timing diagram that illustrates how the graphic data is transferred through the Line Buffer Register logic. Read Select changes every Graphic PRESET which corresponds to every other scan line within the visible zone. When displaying Reg $A$, CLK $A L$ is generated once for every 12 graphic dot positions that are displayed. This shifts a new word to the output of the Shift Register. The word is then loaded into the Video Buffer after the 12 bits of the previous word have been displayed.

Both the $A$ and $B$ Registers are used when graphic data is displayed. One register is loaded from the MD lines with 32 data words; simultaneously, the information in the other register is displayed.

Figure 12-37 Line Buffer Timing for 32 Character Line

Figure 12-38 Line Buffer Timing for 64 Character Line

Figure 12-39 Line Buffer Timing
12.4.2.9 ROM Character Generator Logic - The ROM Character Generator logic is shown in Figure 12-40. Included in the figure is a representation of the alphanumeric Video Buffer Register. The major components of the character generator are three 23-XXA2 1024-bit read-only memories; each is organized to provide 256 4-bit word locations. A functional logic diagram of 23-XXA2 is shown in Figure 12-41.

ASCII-coded characters are gated from the Line Buffer Register to each ROM on the six lines designated BIT 6-11. The five most significant bits of the character, bits $6-10$, are applied to a 1 -of- 32 decoder (Figure 12-41). The ROM ROW CNT signals, generated in the VT8-E timing, are applied to 1 -of- 8 decoders. These three signals select one of 256 4-bit data words. The LSB of the ASCII character, bit 11, is used to gate the 4 -bit word out of the ROM to the Video Buffer Register, a DEC 74965 -bit Shift Register. As Figure 12-40 shows, an odd ASCII character (bit 11 is logic 1) causes the ODD ROM outputs to be selected, while an even character causes the EVEN ROM to be selected. The XTRA ROM provides the necessary fifth bit of the data word and is selected for both even and odd characters.

Remember that ten horizontal scan lines are required to display one character line. During the first two scans, the characters are shifted into the Line Buffer Register. During each of the next eight scans, the Line Buffer Register is recirculated. Bits 6-11 of a character are the same during each scan. The ROM ROW CNT signals change during each scan, cycling through the counts $000_{2}$ to $111_{2}$, where ROM LS ROW CNT is the LSB. Consequently, eight consecutive locations are selected for each ASCII character. The first location is blank, the next seven contain the video information that is ultima tely displayed.

Figure 12-40 ROM Character Generation Logic

Consider the ASCII code for the character H: $001000\left(10_{8}\right)$. Bits 6-10(001 00) are applied to the 1-of-32 decoder during each scan. During Scan Line 3, the ROM ROW CNT signals are low $\left(000_{2}\right)$. The data in the addressed location is 0000 , and no video is displayed. During Scan Line 4, the ROM ROW CNT signals are $001_{2}$. The data in this location is 1000 and is displayed as video. Table $12-8$ relates the eight scan lines, the ROM ROW CNT binary representations, and the data in the addressed locations.

The fifth data bit for each scan is taken from the XTRA ROM. Note that only two outputs are available from this ROM. If the character is even, the output at pin 11 is gated to the Video Buffer; if the character is odd, the output at pin 12 is gated. This ROM is addressed exactly as is the EVEN ROM, as indicated in Table 12-9. The fifth data bit for H is taken from pin 11 of the XTRA ROM. The result is shown below.

| Scan Line | Data Bits Gated to <br> Video Buffer |
| :---: | :---: |
| 3 | 00000 |
| 4 | 10001 |
| 5 | 10001 |
| 6 | 10001 |
| 7 | 11111 |
| 8 | 10001 |
| 9 | 10001 |

The pattern table for each ROM is included in Appendix A. To locate the pattern for an ASCII character, use the following procedure:

## Step

1

2

3

4

## Procedure

If the character is even, divide the 6 -bit binary representation by 2 . The result gives the 6 most significant bits of the location.

Find this location in the Octal Location column of the EVEN ROM pattern table (Table A-1) for 4 of the data bits; find the same location in the Octal Location column of the XTRA ROM pattern table (Table A-3) for the fifth data bit.

For example: When the binary representation of character T, $010100\left(24_{8}\right)$, is divided by 2 , the result is $001010\left(12_{8}\right)$; octal locations $120-127$ of the EVEN and XTRA ROMs contain the video information for the character.

If the character is odd, take the even binary representation immediately preceding the odd binary representation and divide by 2.

Find this location in the ODD and XTRA ROM pattern tables (Tables A-2 and A-3).
For example: To find the pattern for character G, 000111 ( $07_{8}$ ), divide 000110 ( $06_{8}$ ) by 2 ; the result, $000011\left(03_{8}\right)$, identifies locations $030-037$ as yielding $G$.
12.4.2.10 Alphanumeric Video Buffer Control Logic - Figure $12-42$ shows the alphanumeric Video Buffer Control logic. The logic generates the signals that allow the Video Buffer to convert the parallel ROM bits to serial alphanumeric video bits. The logic is shown for 32 characters per line; if 64 characters per line are being displayed, the input clock frequency is 10.92 MHz . Figure $12-43$ shows a timing diagram for the 32 character per line operation. Refer to both figures when reading the logic description.

The 5.46 MHz signal is gated by the logic to produce the LD ALPHA VIDEO BUFFER and CLK ALPHA VIDEO BUFFER signals. The E17 up-counter provides the necessary gating signals. The A, B, and C outputs of E17 are applied to the DEC 7442 BCD-to-Decimal Decoder, E22. When E22 decodes decimal 2, E26C is enabled and the next clock produces a LD ALPHA VIDEO BUFFER signal. When E22 decodes decimal 3 through 7, E26B is enabled
and 5 clock pulses are gated through to produce CLK ALPHA VIDEO BUFFER. A VID EN signal is also generated when E22 decodes decimal 3 through 7. This signal is asserted through the E28 multiplexer when the VIS ZONE L signal is low (note that the VIS ZONE L must be low for E22 to decode decimal 1 through 7).

Because E17 determines character rate, one LD ALPHA VIDEO BUFFER signal, one VID EN signal, and five CLK ALPHA VID BUFFER signals are generated each time a character is shifted from the Line Buffer Register. Remember that 32 SHIFT LINE BUFFER signals are used to recirculate the Line Buffer Register during each scan. Each SHIFT LINE BUFFER signal generates a CLK B signal that shifts a different character to the ROM Character Generator. The character generator produces five bits that represent the character. A LD ALPHA VIDEO BUFFER signal then parallel loads these bits into the Video Buffer Register.

Five CLK ALPHA VIDEO BUFFER signals shift the data bits out of the buffer to the video logic. The VID EN signal enables the video logic to generate signals for the display. Note that the LD ALPHA VID BUFFER signai, designated $A$ in Figure 12-43, loads the character that is shifted from the Line Buffer Register by the CLK B signal designated $A$. While this character is being shifted from the Video Buffer, the new 5 -bit character is being gated to the buffer inputs. Note, also, that the character horizontal spacing is determined by the gating of the 5.46 MHz signal. The character width is represented by five clock pulses ( 0.185 inches for 32 characters/line); the horizontal spacing is represented by the two clock pulses in each character period that are not gated (indicated by the dotted-line CLK ALPHA VIDEO BUFFER pulses). Thus, the spacing is 40 percent of the character width, or 0.074 inches.

Figure 12-44 shows the timing of the alphanumeric Video Buffer Control logic for 64 characters per line. The logic is the same as for 32 characters per line operation.

Figure 12-42 Alphanumeric Video Buffer

Figure 12-43 Character Timing for a 32 Character Line
12.4.2.11 Graphic Video Buffer and Control Logic - The Graphic Video Buffer and Control logic is shown in Figure 12-45. This logic converts the parallel data in the Line Buffer Register to the serial graphic video signals that are applied to the Display Mode Iogic.

When a data word is shifted from the Line Buffer Register, it is applied to the Graphic Video Buffer on the lines designated BIT 11-0. The Video Buffer Register comprises three DEC 7595 4-bit Shift Registers that can be parallel loaded and serial shifted. The DEC 74161 counter, E31, counts down the 5.46 MHz clock pulses to produce an LD GRAPH VID BUFFER signal at a frequency of 455 kHz . The derivation of this signal is shown in the timing diagram in Figure 12-46. Graphic Video Buffer is loaded by CLK GRAPH VID BUFFER when LD GRAPH VID BUFFER is true. This occurs every 12 clock pulses.

When the Video Buffer has been loaded, the LD GRAPH VID BUFFER signal goes low. The DEC 7495 Shift Register cannot be shifted while this signal is high. The next eleven CLK GRAPH VID BUFFER signals shift data out of the register (bit 0 is shifted out first). Note that bit 11 is not shifted from the register since only 11 shift pulses are available. Twelve CLK GRAPH VID BUFFER signals are also used to chop graphic video into distinct dots. This occurs at AND gate E28.

Figure 12-44 Character Timing for a 64 Character Line
12.4.2.12 Visible Field Logic - When an alphanumeric character is to be displayed, the data word transferred to the Line Buffer Register contains not only character information, but also information that controls the visible field and the mode of display. The 12-bit data word is shown in Figure 12-47.

The ASCII-coded character is contained in bits 5-11. Because the VT8-E displays a 64 character set, only bits 6-11 are used to generate character video. Control bits 1 and 2 (referred to as CB1 and CB2) are used to determine the visible field by selectively blanking the video display. Control bits 3 and 4 (referred to as CB3 and CB4) determine how the video is displayed.

Figure 12-48 shows the visible field bits logic. These bits control the visible fieid as outlined in the table accompanying the logic. When J-K flip-flop E44 is set, the BLANK L signal is asserted and the alphanumeric Video Buffer output is inhibited (Figure $12-50$ shows how the BLANK L signal inhibits video). Flip-flop E44 is controlled in an intricate manner that can best be described by a timing diagram. This diagram is shown in Figure 12-49. The timing begins with the start of a character line, represented by the PRESET BRK signal.

Figure 12-45 Graphic Video Buffer Control Logic

Assume that a character in the previous character line had directed the beginning of a blank field; i.e., CB1 of this character was high, while CB2 was low. When this character was shifted from the Line Buffer Register, the next LD ALPHA VID BUFFER signal to occur sets the J-K flip-flop E50B (Figure 12-47). Each succeeding character is either a NOP direction or another BBF direction (both have the same result in the present situation). At the beginning of the present character line, a PRESET BRK signal and a LINE CNT signal occur simultaneously. The leading edge of the LINE CNT signal clears the E44 flip-flop, while the trailing edge of the PRESET BRK signal sets flip-flop E50A. The next LINE CNT signal sets E44 again, because now E50A is set. All three flip-flops would remain in this state throughout the entire character line and into and through each succeeding character line if no EBF direction were received.

However, if an EBF direction is programmed into a data word, the blank field must be ended at the same point in Scan Lines 3 through 10 (although nothing is displayed in Scan Line 3). Assume that character 16 of the present character line directs an end to the blank field. The LD ALPHA VIDEO BUFFER signal corresponding to character 16 clears flip-flops E44 and E50B. For the rest of Scan Line 3, the BLANK L signal is negated. At the start of the fourth scan line, flip-flop E44 has to be set again to blank the first 15 characters. The LINE CNT signal sets the flip-flop, thereby blanking the first 15 characters of Scan Line 4. Again, the sixteenth character says EBF and clears flip-flop E44 (flip-flop B stays clear throughout). This procedure continues until the character line is completed. The second LINE CNT signal of the next character line clears flip-flop E44, which then remains clear until another BBF or an EOS is directed.

Figure 12-46 Graphic Word Timing

Figure 12-47 12-Bit Data Word Format

When the 7-bit ASCII code for line feed (012) is detected, NAND gate E11 is enabled, putting a high on the Jinput of flip-flop E44. The LD ALPHA VID BUFFER signal corresponding to the character 012 sets E44, and the rest of the character line is blanked. It would be contradictory to have the EBF control bits set for the line feed character. The K input of E44 should not be a 1 when the LF (012) character is detected.
12.4.2.13 Display Mode Logic - The Display Mode logic is shown in Figure 12-50. These bits determine how the alphanumeric video is displayed, as outlined in the table accompanying the logic.

When the character is to be displayed with normal intensity, the LD ALPHA VID BUFFER signal clears flip-flops E27A and E27B. NAND gate E30B gates the serial output of the alphanumeric Video Buffer Register to NAND gate E39. If the BLANK L signal is not asserted, the asserted ALPHA VID EN signal and the negated GRAPH L signal gate the five data bits to the VIDEO line. If the character is to be displayed at increased intensity, E27A is set, while E27B is cleared. NAND gate E34C is enabled, in addition to E30B. Inverters E29A and E29B have open-collector outputs. For increased intensity, both gates are inactive. Consequently, the VIDEO output is approximately 5 V . For normal intensity E29B is active and there is a voltage drop in the neighborhood of 3.5 V across the $1 \mathrm{k} \Omega$ resistor. Therefore the VIDEO output is approximately 3.5 V .

Figure 12-48 Display Control Logic

Figure 12-49 BBF and EBF Timing

Figure 12-50 Display Mode Logic

A character is blinked at a 1.875 Hz rate when CB3 is logic 0 and CB4 is logic 1 . The 3.75 Hz signal clocks flip-flop E32. The 0 -output of the flip-flop alternately enables and disables NAND gate E30C, resulting in a VIDEO signal that blinks at the desired rate. If CB3 and CB4 are both logic 1, NAND gate E30A is alternately enabled and disabled by the 3.75 Hz signal. NAND gate E30B is enabled by the character bit, while NAND gate E34B is enabled by the character's bit matrix complement. Thus, the character is displayed as a cursor.
12.4.2.14 Maintenance IOT Logic - The Maintenance IOT logic, shown in Figure 12-51, is enabled at TP3 time if the program executes the DPSM instruction to set the MAINT/GO flip-flop (E56). Refer to Paragraph 12.3 .4 for a description of the IOT instructions enabled when the VT8-E is in the Maintenance mode. These instructions allow the registers and buffers in the VT8-E to be read into the AC. Data may also be transferred from memory using the DPMB instruction. DPMB sets the BRK ROST flip-flop on the M8337 module and the VT8-E executes one Single Cycle Data Break to transfer data from the memory location determined by the Starting Address Register to the Line Buffer.
12.4.2.15 Display Interrupt and Skip Logic - The Interrupt and Skip logic is shown in Figure 12-52. Interrupts are enabled if bit 11 in the AC is 1 when the DPGO instruction is executed by the program. This sets INT ENA and the VT8-E makes an INT ROST when the Real Time Clock (RTC) flag sets at the start of a vertical retrace and signifies the end of the display frame.

The Skip Bus (SKIP L) is asserted at I/O PAUSE time of the DPCL instruction cycle to cause the program to skip the next sequential instruction. The program may at this time switch modes (Alphanumeric/Graphic) without disturbing the visible presentation.

Figure 12-51 Maintenance IOT Logic
12.4.2.16 Bell Logic - The Bell logic is shown in Figure 12-53. BELL EN, a 74123 IC, outputs a 476 ms pulse when the DPBL instruction is executed by the program to enable the 1.56 kHz signal from E11-0 to be applied to the bell. The volume of the tone is adjusted by potentiometer R25 on the M8336 module.

### 12.5 DISPLAY MONITOR CIRCUITS

### 12.5.1 Keyboard Logic

The keyboard (Drawing D-CS-3010166-0-0) provides the VT8-E output to the computer. There are 128 ASCII characters or codes that can be generated by the keyboard. A 2 -way slide switch is mounted on the Keyboard Logic circuitry board to allow the keyboard to be set for upper/lower case ASCII (128 codes) or lower case ASCII (96 codes) operation. Each key has a variable capacitance that is actuated when the key is pressed, causing an excitation voltage to be applied to one side of the capacitor, generating base drive for the transistor amplifier. A sequential scanning technique is used, employing a MOS integrated circuit that consists of an 8-bit and an 11-bit ring counter (to compose an $8 \times 11$ matrix), and circuitry to sample the conductance of each transistor amplifier (one per key). As the two (8-bit and 11 -bit) registers cycle, the 8 -bit counter provides a collector voltage to as many as eleven of the key output amplifiers. Up to eight of the transistor emitters are connected to each of the sensing circuits gated by the 11-bit counter. The two sets of lines that form the $8 \times 11$ matrix are theoretically capable of sampling up to 88 keys.

Figure 12-52 Display Interrupt and Skip Logic

NOTE: Logic is P/O M8336 module.

Figure 12-53 Bell Logic

The VT8-E uses the small 8-key keyboard as an extension of the main keyboard to generate cursor control codes to position the cursor and to erase text. The keys used for cursor control or positioning are: cursor up ( 4 ), cursor down ( $t$ ), cursor left ( -1 ), cursor right ( - ), and HOME. The erase-to-end-of-line (EOL) and erase-to-end-of-screen (EOS) keys are used in conjunction with the LOCK key. The EOL and EOS codes will not be transmitted unless they are used in conjunction with the LOCK key.

### 12.5.2 Motorola CRT Display

The following circuit descriptions refer to the detailed circuit schematic of the Motorola CRT Display Module shown in Drawing D-CS-3010326-0-3.
12.5.2.1 Video Amplifier - The Video Amplifier has four stages incorporating devices Q1, Q2, Q3, and Q4. The first stage, Q1, functions as an emitter follower to provide a high impedance input with the $75 \Omega$ terminating resistor removed. The high impedance operation permits use of bridging connections to drive a number of monitors from the same signal source. The low output impedance of the first stage permits use of a low resistance contrast control which furnishes flat video response over its entire range without the need for compensation. The collector output of Q1 is used to drive the Sync Separator. C3 provides high frequency roll off to limit the collector output to the band-width required to pass synchronization signals. O 2 is a common emitter stage and is directly coupled to $\mathrm{Q4}$. Q 3 and Q 4 are connected in a cascade configuration. This common emitter/common base connection greatly reduces the effect of Miller capacity compared with a conventional single transistor video output stage. C6 provides a ground for video at the base of Q3, the grounded base transistor of the video output cascade pair.

The video bias control (R10) is used to set the quiescent collector voltage of $\mathbf{Q 3}, \mathrm{C}, \mathrm{C} 7, \mathrm{C}$, and R15 for high frequency compensation. Restoration of dc voltage is accomplished by setting the video bias control so that sync tips, which are negative-going at the collector of Q 3 , just go into saturation. Variations in video drive result in variations in the base current of O 2 during sync time due to the low load reflected back when Q 3 is saturated. The charge on C4 will thus depend on the amplitude of output collector current during sync time. The result is a clamping action which holds sync tips at the same level despite video signal variations. The Video Amplifier output is direct coupled to the control grid of the CRT. R18 is used to isolate $\mathbf{Q 3}$ from transients that may occur as a result of CRT arcing.
12.5.2.2 Sync Separator - The Sync Separator uses a single stage, 05 , to recover sync from the composite video signal. A single-stage Sync Separator is adequate due to the high impedance of the following stages. The video input to the Sync Separator is black positive. C11 is charged by the peak base current that flows when the positive peak of the input takes $\mathbf{Q 5}$ to saturation. This charge depends on the peak-to-peak input to Q 5 and thus makes the bias for O 5 track the amplitude of the input signal. As a result, O 5 amplifies only the positive peaks of the input signal. The initial bias current through R24 sets the clipping level.
12.5.2.3 Phase Detector - The Phase Detector uses two diodes in a key clamp circuit. Two inputs are required to generate the required output, one from the Sync Separator and one from the horizontal deflection system. The required output must be of the correct polarity and amplitude to correct phase differences between the input sync and the horizontal time base. The horizontal collector pulse is integrated into a sawtooth by R45 and C15. During sync time, both diodes in D7 conduct, shorting C15 to ground.

The sawtooth on C15 is thus clamped to ground at sync time. If the horizontal time base is in phase with the sync, the sync pulse will occur when the sawtooth is passing through its ac axis and the net charge on C15 will be 0 (Figure 12-54). If the horizontal time base is lagging the sync, the sawtooth on C 15 will be clamped to ground at a point negative from the ac axis. This will result in a positive de charge on C16 (Figure 12-54). This is the correct polarity to cause the Horizontal Oscillator to speed up to correct the phase lag.

Likewise, if the horizontal time base is leading the sync, the sawtooth on C 15 will be clamped at a point positive from its ac axis, resulting in a negative charge on C 15 . This is the required polarity to slow the horizontal oscillator (Figure 12-54). R33, C17, C16, and R32 comprise the Phase Detector Filter. The bandpass of this filter is chosen to correct the Horizontal Oscillator phase without ringing or hunting.

Figure 12-54 CRT Horizontal Oscillator Waveforms
12.5.2.4 Horizontal Oscillator - Q 6 is employed in a modified type of Hartley oscillator. The operating frequency of this oscillator is sensitive to its base input voltage. This permits control by the output of the Phase Detector and also by the setting of the horizontal hold control. The horizontal hold range is set by adjusting the core of L1.
12.5.2.5 Pulse Shaper and Horizontal Drive - Q 7 is used as a buffer stage between the Horizontal Oscillator and the Horizontal Driver. It provides isolation for the Horizontal Oscillator as well as a low impedance driver for the Horizontal Driver. R38 and C20 form a time constant which shapes the oscillator output to the required duty cycle (approximately 50 percent), to drive the Horizontal Output circuitry. The Horizontal Driver stage, 08, operates as a switch to drive the Horizontal Output transistor through T1. Because of the low impedance drive and fast switching times furnished by Q7, very little power is dissipated in Q8. C21 and R42 provide damping to suppress ringing of the primary to T 1 when Q 8 goes into cutoff.
12.5.2.6 Horizontal Output - The secondary of T1 provides the required low drive impedance for Q9. R44 and C 24 form a time constant for fast turn-off of the base of 09.09 operates as a switch that, once each horizontal period, connects the supply voltage across the parallel combination of the horizontal deflection yoke and the primary of T2. The required sawtooth of the deflection current through the horizontal yoke is formed by the L-R time constant of the yoke and output transformer primary. The Horizontal Retrace pulse charges C27 through D2 to provide operating voltage for G2 of the CRT. Momentary transients at the collector of Q9, should they occur, are limited to the voltage on $C 27$, since $D 2$ will conduct if the collector voltage exceeds this value.

The damper diode, D1, conducts during the period between retrace and turn-on of Q9. C28 is the retrace tuning capacitor. C29 blocks dc from the deflection yoke. L3 is a magnetically-biased linearity coil that shapes deflection current for optimum trace linearity. L4 is a series width control. C31 and R49, C42 and R68 are damping network components for the linearity and width controls. C43D is charged through D5 developing the video supply voltage.
12.5.2.7 Vertical Oscillator Driver and Output - Sync from the collector of Q5 is integrated by R26 and C35. Q10 and 011 are connected as a regenerative switch. The series combination of C37 and C38 charges through R58 and D3 until Q10 turns on. This occurs when the emitter of Q10 exceeds its base voltage and causes current to flow into the base of Q11, turning that device on. When Q10 and Q11 conduct, C37 and C38 are discharged to nearly $0 . \mathrm{Q} 10$ and $\mathbf{Q 1 1}$ then shut off and the cycle repeats. The setting of the vertical hold control determines the repetition rate of the charge and discharge of C37 and C38. The waveform generated is a positive-going ramp or sawtooth with a fast retrace to 0 . D3 provides a small incremental voltage above ground to overcome the forward base-emitter drop of the two following stages. Q12 is an emitter follower used to transform the high impedance drive sawtooth to a low impedance drive for Q13.

T3 matches the collector of 013 to the vertical yoke. When Q13 is cut off during Vertical Retrace, a high voltage pulse is developed across the primary of T3. To limit this pulse to a safe value a varistor, R81, is connected across
the primary. R66 and C41 provide damping to shape the collector pulse so it may be used for retrace blanking. Since the primary impedance of T3 decreases with current, the degree to which the primary shunts the reflected load impedance varies with collector current. This would result in severe vertical non-linearity unless some compensation is employed.

Resistors R60 and R59 couple the emitter voltage of Q13 to the junction of C37 and C38. Since this path is resistive, the waveform coupled back will be integrated into a parabola by C38. This results in a pre-distortion of the drive sawtooth as shown in Figure 12-55. This is done to compensate for the non-linear charging of C37 and C38 and the changing impedance of the primary of T3. An additional feedback path through R62 and C40 serves to optimize the drive waveshape for best linearity.

8E-0685

Figure 12-55 CRT Vertical Oscillator Waveforms
12.5.2.8 Retrace Blanking - Both Vertical and Horizontal Retrace blanking are provided by positive pulses applied to the CRT cathode. The collector pulse from the Horizontal Output transistor is placed across R23 through R46. The vertical collector voltage is differentiated by C3O to remove the sawtooth portion of the waveform. The remaining pulse appears across R23. The mixed vertical and horizontal pulses on R23 are coupled to the CRT cathode by C10.
12.5.2.9 Power Supply - The regulated power supply uses a series pass circuit. Q16 is the series pass transistor, Q14 is the driver, and Q15 is the reference amplifier. The output voltage of the regulator appears at the emitter of Q16 and is fed into a voltage divider consisting of R71, R74, and R73. The voltage appearing on the arm of potentiometer R74 is used as an error input to Q15. R74 is thus used as the output voltage adjustment.

Zener diode D13 establishes a reference voltage at the emitter of Q15. R72 establishes the minimum bias current for D13 to ensure proper Zener operation.

The voltage at the arm of R74 is compared with the reference voltage at D13 by $\mathbf{Q 1 5}$. If the voltage at the base of Q15 increases due to an increase in input voltage to the power supply for example, Q15 conducts more current. This decreases the current available to the base of Q14, so Q14 and Q16 conduct less current, resulting in less voltage at the emitter of Q16. In this manner, input voltage changes are reduced by the overall gain of the regulator, which is quite high. R79 reduces the power dissipation in Q16 by carrying some of the supply current. This does not impair regulation over the operating range of the power supply due to the large amount of gain available.

## SECTION 5 MAINTENANCE

### 12.6 INTRODUCTION

VT8-E maintenance theory is directed to the module replacement level. The maintenance effort is divided into two basic categories: preventive maintenance and corrective maintenance.

Preventive maintenance consists of routine periodic checks such as visual inspections, standard maintenance procedures that involve cleaning and lubricating, and diagnostic tests that expose possible weakening conditions to allow corrective action to be taken, eliminating the causative factor(s) of possible failures.

Corrective maintenance consists of isolating the fault or problem and making necessary adjustments and/or replacements when a malfunction occurs. This involves the use of diagnostic routines prepared on paper tape and designed to test the functional units of the system. The procedures and techniques of periodic checking aid in fault isolation. Power requirements can be checked through the checkout procedures for power requirements contained in Paragraph 12.2.2.

### 12.6.1 Equipment Required

Maintenance procedures for the VT8-E Video Display and Control require the standard equipment (or equivalent), standard hand tools, and test probes listed in Table 12-10.

Table 12-10
Equipment Required

| Equipment | Manufacturer | Designation |
| :--- | :--- | :--- |
| Multimeter | Triplett or Simpson | Model 630-NA or 620 |
| Oscilloscope | Tektronix | Type 453 |
| X10 Probe | Tektronix | P6010 |
| Recessed Tip | Tektronix | $013-0090-00$ |
| Diagnostic Self-Test |  |  |
| $\quad$ Routines |  |  |

### 12.6.2 Diagnostic Programming

The diagnostic routines, supplied as paper tapes, are used to test the various VT8-E functions and modules. A complete description with instructions is provided with each tape.

### 12.6.3 Preventive Maintenance

Preventive maintenance consists of tasks performed periodically; its major purpose is to prevent failures caused by minor damage or progressive deterioration due to aging. A preventive maintenance log book should be established and necessary entries made according to a regular schedule. This data, compiled over an extended period of time, can be very useful in anticipating possible component failures resulting in module replacement on a projected module or component reliability basis.

Preventive maintenance tasks consist of mechanical and electrical checks. All maintenance schedules should be established according to the environmental conditions at the particular installation site. Mechanical checks should be performed as often as required to allow the fan and air filter to function efficiently. All other preventive maintenance tasks should be performed on a regular schedule determined by reliability requirements. A recommended schedule is every 600 operating hours or every four months, whichever occurs first.
12.6.3.1 Mechanical Checks - Use the following procedure to perform a mechanical check on the equipment.

Step
1

4

5

2 Clean the exterior with a clean cloth moistened in a mild detergent. Only a very soft cloth should be used to avoid scratching the protective screen used on the face of the CRT.

3 Clean the interior using a vacuum cleaner and ensure that the cabinet air exhaust vents are thoroughly clean and unobstructed to promote adequate cooling. Should the vents become obstructed, premature component failure may occur due to an increase in the VT8-E internal temperature.

## Procedure

Unplug the VT8-E main power and remove the cover.

VT8.E internal temperature.
Inspect all wiring and cables for cuts, breaks, fraying, deterioration, kinks, strain, and mechanical security. Tape, solder, or replace any defective wiring or cable covering.

Inspect the following for mechancial security: jacks, connectors, keyboard, etc. Tighten or replace as required.

### 12.6.4 Troubleshooting

12.6.4.1 System Troubleshooting - Begin troubleshooting by repeating the operation in which the malfunction was initially observed, using the same program or function. Thoroughly check the program for proper settings and determine if the fault is definitely located in the VT8-E.

If the fault is isolated to the VT8-E, but cannot be immediately localized to a specific logic function, an effort should be made to further isolate the fault to one of the VT8-E modules, e.g., keyboard, M8335 module, CRT module, etc. Some helpful aids during functional analysis are the VT8-E engineering drawings, circuit schematics, timing diagrams, and the applicable VT8-E diagnostic programs.
12.6.4.2 Module Troubleshooting - Once the fault has been isolated to a specific module, carefully remove the suspected module. Inspect the receptacle for wear or damaged contacts. When the operability of the module is verified, repair the faulty module or replace it with a module known to be operating properly and run the last diagnostic program. If the system performs properly, return the system to an operating status and log an entry to record all pertinent data concerning the fault or malfunction. When the individual defective part(s) within a module is located and repaired or replaced, the module should be verified by a validation test.
12.6.4.3 VT8-E Assembly/Disassembly - The following procedures are provided for removal, replacement, and installation of the various VT8-E modular components. Special and cautionary notes contained within the procedures afford special attention and should be adhered to. Only procedures for the removal of the VT8-E modular components are provided; for installation, the procedures should be performed in their reverse order.
12.6.4.3.1 VT8-E Module Boards - The M8335, M8336, or M8337 module boards should be inserted straight into the OMNIBUS, never at an angle. When inserting a module board be certain it is fully seated in the OMNIBUS.
12.6.4.3.2 Cover Removal - The VT8-E cover is secured with four Phillips-head screws. Screw locations are center-front, center-rear, and midway on the two sides. The screws are inserted up through the lower casting and into four cover-retaining brackets. To remove the cover, remove the four retaining screws and lift the cover off.

NOTE
When the cover is removed, the 3 -position interlock switch on the left-hand side (viewing from the front) will go from the fully depressed position (ON) to the middle position (OFF) and must be pulled up to the third position (ON).

To install the cover, place the cover back on the lower casing, insert and tighten the four Phillips-head retaining screws. The interlock switch should be in the fully depressed (ON) position.
12.6.4.3.3 VT8-E Keyboards Removal - The VT8-E contains two keyboards, a large teletypewriter-type keyboard, and a small 8-key cursor control keyboard. The small keyboard is secured by four Phillips-head screws that are inserted down through the four corners of the mounting board into the mounting bracket. The large keyboard is secured by four Phillips-head screws that are inserted down through the keyboard mounting bracket. These four screws should not be confused with the smaller and brighter Phillips-head screws that secure the keyboard to the keyboard logic board. The smaller, brighter screws should not be removed.

Use the following procedure to remove the small keyboard:

1
Disconnect the ribbon cable from the small keyboard input connector.

2
Remove the four Phillips-head retaining screws from the four corners of the small keyboard mounting board.

3
Slide the keyboard to the left and lift it out.
Use the following procedure to remove the large keyboard:
Step Procedure
1 Disconnect the 44-pin Berg connector from the keyboard output connector.
2 Remove the four, larger keyboard Phillips-head retaining screws from the keyboard mounting bracket and remove the keyboard
12.6.4.3.4 CRT Removal - The CRT is secured to the VT8-E lower casting with four Phillips-head screws that are inserted through the bottom of the VT8-E and into the bottom four corners of the CRT chassis. Use the following procedure to remove the CRT:

## CAUTION

Protective goggles and heavy gloves should be worn when removing and/or carrying the CRT. Never grasp the CRT by the neck, nor chip or scratch any part of the tube.

Press the interlock switch down to ensure main power is off.
2 Viewing the VT8-E from the front, locate (15-pin and 12-pin) Mate-N-Lok connectors P1 and P2 on the lower right-hand side of the CRT chassis and disconnect both connectors.

3
Locate and remove the four Phillips-head retaining screws on the bottom of the VT8-E, used to secure the CRT chassis to the lower casting.

## NOTE

Upon removal, the CRT should be placed face-down on a soft clean cloth or pad. Under no circumstances should the CRT be grasped by the neck

4
Lift the CRT out of the lower casing.
