1. ABSTRACT

The PDP-8E Extended Memory Data & Checkerboard Test is designed to detect memory failure due to sense-line noise under worst case conditions. The four worst case patterns provided will generate worst case noise conditions in all standard and specially purchased PDP-8E core stacks, and will test systems equipped with from 8K to 32K words of core memory. The All 0's and All 1's patterns are provided to identify basic memory failures. Automatic program relocation is provided in order to test all memory fields from each memory field. Teletype printouts are provided for error identification, and the operator is given a degree of control over the program by various switch register settings.

2. REQUIREMENTS

2.1 Equipment

A PDP-8E Computer equipped with at least 8K of core memory.

2.2 Storage

The program occupies core locations 0000 to 4777 and 6000 to 7177 of the present field.

2.3 Preliminary Programs

The Binary Loader must be in memory. Also, all diagnostics for a basic 4K PDP-8E must have been previously run successfully.

3. LOADING PROCEDURE

Load the program with the Binary Loader (BIN). The program may be loaded into any field.

4. OPERATING PROCEDURE

To start the program:

- A. Set the SR to the IF and DF of the field that contains the program.
- B. Press key EXTD ADDR LOAD.
- C. Set the SR equal to 0200.
- D. Press keys ADDR LOAD, CLEAR, and CONT. A setup SR message will be printed.

E. Set the SR for desired operation according to the following table.

SWITCH	0 (down)	1 (up)
SR00	continue after error	halt after error
SR01	timeout errors	inhibit error timeouts
SR02	normal	TTY bell on error
SR03	relocate program	inhibit program relocation
SR04	normal	change field limits
SR05	normal	halt after current test
SR06-08	starting field limit (0-7)	
SR09-11	ending field limit (0-7)	

F. Press key CONT.

4.1 Detailed SR Explanation

- SR00-02 SR02, if set, will ring the TTY bell once for each error. SR00 and SR01 have no effect with SR02 set.
- SR03 SR03 may be set or reset at any time and the program will act accordingly.
- SR04 SR04 allows the operator to change the field limits as defined by SR06-11.
- SR05 SR05 is normal halt for program.
- SR06-08 These switches define the starting field limit (normally 0).
- SR09-11 These switches define the ending field limit (normally 7).

4.2 Example of selecting fields for test

- Example 1: SR = 0007, 28K system
Fields selected for testing are 6, 5, 4, 3, 2, 1, 0.
- Example 2: SR = 0004, 28K System
Fields selected for testing are 4, 3, 2, 1, 0.
- Example 3: SR = 0022, 28K System
Fields selected for testing are 2 (no relocation will occur).
- Example 4: SR = 0041, 28K System
Fields selected for testing are 6, 5, 4, 1, 0.
- Note 1: Fields not in the system are automatically deselected as in Example 1. Field 7 is not present, therefore, not selected.
- Note 2: Do not select a field that contains a ROM.

Note 3: A single field can be selected for testing providing the program is not in that field as in Example 3.

Note 4: Any field or group of fields can be by-passed as in Example 4. Fields 2 and 3 are not selected, Field 7 is not present.

5. ERRORS

A Test Error will occur anytime the data written does not match the data read. A Relocation Error will occur if the relocation comparison check fails.

5.1 Test Error Typeouts

For the first error encountered a header will be typed out followed by the pertinent data. For all subsequent errors, only the pertinent data will be typed. The format is as follows:

PR.LOC.. FAIL. ADR..GOOD..BAD..PATTERN

PR LOC = the program address where the error JMS occurred.
(Includes Field).

FAIL ADR = the address of the location in error. (Includes Field).

GOOD = the data that was written.

BAD = the data that was read.

PATTERN= the present test pattern and the number of times it was complemented.

NC (Not Complemented).

1C (One Complementation).

2C (Two Complements).

5.2 Relocation Error Typeouts

All relocation errors are in the following format:

XXXXX RELOCATION ERROR AT LOCATION YYYYY

XXXXX = the program address where the error JMS occurred.
(Includes Field).

YYYYY = the address of the location in error. (Includes Field).

Note: After each error print-out the program continues on with the next sequential memory location.

5.3 Parity Error Typeouts

If the 8E System contains a Parity Option the interrupt will be turned on to allow Parity errors when the program is executing from Field 0. The following 3 typeouts can occur with a Parity Option:

- A. Parity Error, LOC 0=XXXX TSTAD=XXXXX (present Pattern)
- B. Interrupt from Keyboard
- C. Unwanted Interrupt Occurred

6. RESTRICTIONS

6.1 Starting Restrictions

The program may be restarted at any time from location 0200 or 0202 of the field the program is presently in.

6.2 Operating Restrictions

The parity error typeout can not be inhibited.

7. EXECUTION TIME

The time to write and read all six patterns in one field is approximately 6 seconds.

During program execution a 5 will be typed on the TTY approximately every 5 minutes of program run time. This allows the operator to determine approximate run time before a failure occurred.

8. SCOPE LOOPS

8.1 Scope Loop 1

This scope loop does a read, complement, write on the address specified by the SR. The address being looped on can be changed simply by changing the switch setting. The previous address will be left with its original content.

- A. Set the SR to the INSTRUCTION FIELD that the program is in and the DATA FIELD wanted to test.
- B. Press key EXT D ADDR LOAD.
- C. Set the SR equal to 6000.
- D. Press key ADDR LOAD.
- E. Set the SR equal to the address to test.
- F. Press keys CLEAR, and CONT.

8.2 Scope Loop 2

This scope loop does a read, complement, write on the two addresses input via the SR. To change the addresses, the Loop must be restarted.

- A. Set the SR to the INSTRUCTION FIELD that the program is in and the DATA FIELD wanted to test.
- B. Press key EXTD ADDR LOAD.
- C. Set the SR equal to 6200.
- D. Press keys ADDR LOAD, CLEAR, and CONT.
- E. Follow directions that are typed out.

8.3 Scope Loop 3

This scope loop does a read, complement, write on the group of addresses input via the SR. The starting address specified must be less than the ending address specified.

- A. Set the SR to the INSTRUCTION FIELD that the program is in and the DATA FIELD wanted to test.
- B. Press key EXTD ADDR LOAD.
- C. Set the SR equal to 6400.
- D. Press keys ADDR LOAD, CLEAR, and CONT.
- E. Follow directions that are typed out.

8.4 Scope Loop 4

This scope loop does a read, complement, write on the address input via the SR using the data specified by the SR. The data can be changed simply by changing the switch setting.

- A. Set the SR to the INSTRUCTION FIELD that the program is in and the DATA FIELD wanted to test.
- B. Press key EXTD ADDR LOAD.
- C. Set the SR equal to 6600.
- D. Press keys ADDR LOAD, CLEAR, and CONT.
- E. A message will be typed out to set the SR to the selected address.

- F. Set SR to the selected address and depress CONT.
- G. Set SR to selected data (Scope Loop is cycling).

8.5 Scope Loop 5

This scope loop does a read, complement, write on the group of addresses input via the SR using the data specified by the SR. The starting address specified must be less than the ending address specified.

- A. Set the SR to the INSTRUCTION FIELD that the program is in and the DATA FIELD wanted to test.
- B. Press key EXTD ADDR LOAD.
- C. Set the SR equal to 7000.
- D. Press keys ADDR LOAD, CLEAR, and CONT.
- E. Follow the typed out message that inputs the address selections.
- F. Set SR to selected Data (Scope Loop is cycling).

Note 1: The address(s) specified will be looped until stopped by the operator with key HALT. No error checking is done. To resume normal operation, restart program at address 0200 or 0202 of the current instruction field.

9. PROGRAM DESCRIPTION

9.1 Test Patterns

The following test patterns are employed by the program:

- A. Basic All 0's pattern.
- B. Basic All 1's pattern.
- C. 0000-7777 worst case checkerboard pattern.
- D. 7777-0000 worst case checkerboard pattern.
- E. 2525-5252 worst case checkerboard pattern.
- F. 5252-2525 worst case checkerboard pattern.

9.2 Program Relocation

Program relocation is governed by the status of SR bit 3 or by the fact that only one field is selected for testing. With SR bit 3 down (0 position) program relocation occurs each time the test pattern and its complement have been completely tested in each selected field. The program first relocates to the highest order 4K field under test. The program keeps relocating to the next lower field under test until it reaches the lowest order field under test. The testing and relocation cycle is then repeated. The contents of the entire field are relocated which enables any other information (RIM-BIN) to be carried with the program.

The program provides a degree of protection for itself by remembering all fields where errors occur. When a faulty field is next in sequence to contain the program, the program will skip the faulty field and relocate to the first lower order field which is error free. If all other selected fields are faulty, program relocation will not take place.

During relocation a comparison check is made to insure no program loss.

9.3 Test Procedure

- A. Write the pattern in all selected fields (each location is then treated as follows):
- B. Read-Write the location 11 times.
- C. Read-Write-Test the location (NC).
- D. Read-Write the location 11 times.
- E. Read-Complement-Write the location.
- F. Read-Write the location 11 times.
- G. Read-Write-Test the location (1C).
- H. Read-Write the location 11 times.
- I. Read-Complement-Write the location.
- J. Read-Write the location 11 times.
- K. Read-Write-Test the location (2C).
- L. Go on to next location repeating B-K.
- M. Go on to next pattern repeating A-L when all locations of all selected fields are completed.

For further understanding of how the test is performed, refer to the listing.

The worst case checkerboard pattern consists of alternating 4 memory cores containing 0000 and 4 memory cores containing 1111 on a memory plane. This pattern is reversed every 400 octal locations. (This test pattern is generated according to the stringing of the stack and the wiring of the memory system. It is the same pattern for all 8E stacks).
